Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

User information

Symbols

The following standard symbols are used in Statistics Canada publications:

- . not available for any reference period
- .. not available for a specific reference period
- ... not applicable
- 0 true zero or a value rounded to zero
- 0^s value rounded to 0 (zero) where there is a meaningful distinction between true zero and the value that was rounded
- P preliminary
- r revised
- x suppressed to meet the confidentiality requirements of the *Statistics Act*
- E use with caution
- F too unreliable to be published

Acknowledgements

It is a new team that has worked on the planning, production, analysis and dissemination of this updated set of population projections for Canada, provinces and territories. I would like to thank first Patrice Dion, manager of the projections, as well as Jonathan Chagnon and Jean-Dominique Morency, who have done most of the work related to the project.

Other persons from Demographic analysis and projections section as well as from Demography Division have been closely involved with the projections, such as Éric Caron Malenfant, Carol D'Aoust, Hubert Denis, Julie Faubert, Stéphane Gilbert, Waldemar Gorniak, Marjorie Kirk, Anne Milan, Jean-François Naud and Geneviève Ouellet.

I also wish to thank all partners that have been asked to provide comments on the assumptions and scenarios: provincial and territorial focal points, Citizenship and Immigration Canada as well as the various internal and external committees associated with Demography Division. I am also thankful to our many clients for their recommendations and comments over the last few years.

The final version of this document has been reviewed by Johanne Denis, Rosemary Bender and Réjean Lachapelle.

Laurent Martel
Chief, Demographic Analysis and Projections Section
Demography Division

Preface

Since 1974, Statistics Canada's Demography Division has been publishing population projections for Canada, the provinces and the territories. The assumptions and scenarios underlying the projections are widely consulted by many partners of Statistics Canada, including provincial and territorial focal points, other federal departments—notably Citizenship and Immigration Canada—and various internal and external committees of Demography Division.

Following numerous comments from these partners as users of population projections, a short-term scenario is now available; all its assumptions (except the one concerning mortality) reproduce the behaviours observed during the most recent available year of the Demographic Estimates Program. Rather than projecting behaviours over a long period that are based on a single year of observation, the projection horizon for that scenario was limited to five years. This short-term scenario enables users to consider what the Canadian population might become if the very recent situation continues.

The population projections are not predictions, on any account. Instead, they are based on a series of assumptions which, once summarized in a few scenarios that are intended to be both plausible and relevant, offer a range of possibilities as to how the Canadian population will evolve in the future. Beyond the fact that they serve to shed light on the long-term consequences of the demographic changes under way, projections are useful for planning future needs and developing policies in response to demographic changes. Accordingly, the projections are intended for a wide range of users including the federal government, provincial, territorial or municipal governments, research groups, academics, interest groups, international and non-governmental organizations, educational institutions and the general public.

A final point to note is that another series of population projections was recently produced by Demography Division and has been available since March 9, 2010: *Projections on the Diversity of the Canadian Population, 2006 to 2031*. These projections of diversity differ in many respects from the projections for Canada, the provinces and the territories: they are produced by means of a microsimulation method, and their basic geographic level focuses on Canada's 33 census metropolitan areas (CMAs). In addition, they contain a number of variables reflecting the ethnocultural diversity of the population: visible minority status, religious denomination, mother tongue, generation status and place of birth. Where possible, the assumptions for these projections were harmonized with those in the present projections to ensure the best possible consistency between the two data series. However, their results differ based on their respective objectives and their method of calculation; therefore, users are encouraged to be aware of these differences between the two series of projections.

Table of contents

Highlights	16
Introduction	18
Section 1 Method and assumptions	19
1.1 Method	19
1.2 Base population	19
1.3 Fertility	19
1.4 Mortality	23
1.5 International immigration	25
1.6 Emigration	27
1.7 Non-permanent residents	28
1.8 Interprovincial migration	29
Section 2 Selection of scenarios	38
Section 3 Analysis of the results of the long-term projections	40
3.1 Cautionary note	40
3.2 Growth of Canada's population from 2009 to 2061	40
3.3 Components of growth	41
3.4 Age structure of the Canadian population	44
3.5 Growth of the population of the provinces and territories from 2009 to 2036	55
3.6 Age structure of the population of the provinces and territories	57
3.7 Sensitivity of results to projection assumptions	72
Section 4 Analysis of the results of the short-term projections	75
Section 5 Analysis of previous editions of the projections	77
Section 6 Conclusion	80

3.3	Demographic weight of the provinces and territories observed (2009) and projected (2036) according to six scenarios	56
3.4	Median age observed (2009) and projected (2036) according to six scenarios, Canada, provinces and territories	57
3.5	Percentage of persons aged 65 years or over observed (2009) and projected (2036) according to six scenarios, Canada, provinces and territories	58
3.6	Percentage of variation of projected population in 2036 according to the adopted immigration assumption in comparison of the medium-growth scenario (M1)	73
4.1	Assumptions of fertility, mortality, immigration, emigration, non-permanent residents and interprovincial migration	75
4.2	Observed (2009) and projected (2014) population, average annual growth rate and components of population growth according to the short-term scenario, Canada, provinces and territories	76

Highlights

Population count and population growth in Canada

- According to selected scenarios, there would be between 40.1 and 47.7 million people in Canada by 2036 and between 43.0 and 63.8 million by 2061, in comparison to 33.7 million in 2009. According to the medium-growth scenario, the Canadian population would reach 43.8 million by 2036 and 52.6 million by 2061.
- According to the medium-growth scenario, natural increase would remain positive over the whole projection period, the number of deaths never exceeding the number of births. Only in the low-growth scenario would natural increase become negative, a situation that would occur by 2030/2031.
- Migratory increase would be the main driver of population growth in all scenarios.

Age structure of the Canadian population

- Population aging in Canada would accelerate between 2010 and 2031, a period during which all baby boomers would reach age 65. Population aging would continue after 2031, but at a slower pace.
- According to all selected scenarios, the proportion of seniors aged 65 years or over would continue to increase in the future. This group would represent between 23% and 25% of the population by 2036 and between 24% and 28% by 2061, compared to 14% in 2009.
- By 2036, the number of seniors would be more than double the number observed in 2009 and would vary between 9.9 and 10.9 million persons. By 2061, their number would vary between 11.9 and 15.0 million.
- According to all selected scenarios, the number of people aged 65 years or over would surpass the number of children aged less than 14 years or under. This shift, a first in the history of the Canadian population, would occur between 2015 and 2021.
- According to all selected scenarios, the proportion that represents the working-age population among the total population would decrease progressively up to 2036 to reach about 60% and would then remain fairly stable. In 2009, the proportion that represents the working-age population was 69%.
- In 2009, for every 100 people in the working-age population, there were 24 children aged 14 years or under and 20 people aged 65 years or over. According to the medium-growth scenario, there would be 26 children and 39 seniors per 100 working-age people in 2036.
- According to the medium-growth scenario, the population aged 80 years or over would be 2.6 times higher in 2036 compared to 2009, and 3.9 times by 2061. It could reach 3.3 million persons by 2036 and 5.1 million by 2061.
- According to the scenarios, median age would vary between 42 and 45 years by 2036 and between 42 and 47 years by 2061, compared to 40 years in 2009.

Population of the provinces and territories

- Ontario and British Columbia would show an annual population growth higher than the national average in all six scenarios. Therefore, their demographic share among the Canadian population would increase up to 2036.
- In each scenario, all provinces and territories would experience an increase in their population, except Newfoundland and Labrador where a lower population in 2036 than in 2009 would be observed under the low-growth scenario or some medium-growth scenarios.

Age structure of the provinces and territories

- The highest median ages in Canada by 2036 would be in the Atlantic provinces regardless of the selected scenarios, while the lowest median age would be in Nunavut and Northwest Territories.
- The gap between the highest and lowest provincial median age would vary between 8 and 10 years by 2036. This gap is slightly higher than the one observed in 2009, at about 7 years.

Introduction

Canadian demography has undergone many changes recently. First, the fertility of all Canadian provinces has increased since 2005, as in many other industrialized countries. Second, the origin of immigrants to Canada has changed, with the share of immigration from China and India declining slightly in favour of immigration from other continents, especially the Americas. Also, the number of non-permanent residents admitted to Canada has substantially increased in recent years. And finally, some provinces that traditionally lost ground in their migratory exchanges with the other provinces are now registering positive net interprovincial migration.

In this context, updating the population projections for Canada, the provinces and the territories is especially important. As their base population, these new projections use Statistics Canada's population estimates as of July 1st, 2009, and they cover the period from 2009 to 2036 for the provinces and territories and from 2009 to 2061 for Canada as a whole. These projections are available by age, sex and province or territory of residence and for seven growth scenarios.

The first part of the document describes the method, assumptions and scenarios developed for these new projections. The second part presents the main results of many scenarios of future change, providing a plausible range of possibilities regarding the future course of Canada's population. The analysis, which deals with the size, growth and age structure of the population, is presented first at the national level, and then at the level of the provinces and territories. The sections that follow include an analysis of the sensitivity of the results to the different projection assumptions and a review of past projections. Lastly, tables presenting the results of the seven projection scenarios are appended (Statistical tables).

Other, more detailed data are also available in other products, especially on CANSIM on the Statistics Canada website, or on a CD-ROM available from Statistics Canada's Demography Division. Finally, customized assumptions and scenarios are always available on request. Those interested should contact the client services unit of Statistics Canada's Demography Division.

Section 1

Method and assumptions

1.1 Method

The population projections for Canada, provinces and territories are produced by means of the components method, which has been used for a number of decades both by Statistics Canada and by other provincial, territorial, national and international statistics agencies to project particular characteristics of a population—primarily age, sex and place of residence. Several assumptions are formulated for each component of growth—fertility, mortality, immigration and emigration. Once applied in the form of numbers, rates and quotients to the base population, these assumptions generate births, deaths, immigrants and emigrants. The population of the following year is then obtained by simple demographic accounting, with births and immigrants being added to the base population while deaths and emigrants are subtracted.

The projection model used by Statistics Canada takes account of the interaction between demographic phenomena. For this purpose, the model first constructs a transition matrix that combines the various rates associated with events (births, deaths, immigration, emigration, internal migration). This transition matrix is then applied to the population at the start of the period to obtain the population at the end of the period. This stage also serves to calculate the mid-year population for each year, a figure that is needed in order to calculate events observed during a given year.

Lastly, the population of each province and territory is projected individually, so as to take regional distinctiveness into account. These projected populations can then be summed to obtain a consistent projection of the population of Canada as a whole.

1.2 Base population

The base population for these projections is obtained from the preliminary postcensal estimates of the population on July 1st, 2009 as calculated by Statistics Canada's Demography Division. These estimates by age (from 0 to 99 years and 100 years or over), sex and province/territory of residence are based on the 2006 Census and are adjusted to take account of net undercoverage by age, sex and province/territory. On July 1st, 2009, the Canadian population was estimated at 33,739,859. Table 1.1 shows the population figures for the various provinces and territories. These estimates are also available at no charge on the Statistics Canada website.

Table 1.1
Preliminary postcensal estimates, Canada, provinces and territories, as of July 1st 2009

	Number
Canada	33,739,859
Newfoundland and Labrador	508,925

1.3 Fertility

Because fertility has a major effect on the size and the age structure of a population, three assumptions are usually formulated for this component. This edition of the population projections is no exception, and these assumptions are based on a careful examination of historical and recent trends at the provincial, territorial, national or international level. The assumptions cover both the future level of fertility and its tempo (mean age at childbearing).

1.3.1 Assumptions

At the national level, the medium assumption used for these projections is a total fertility rate of 1.70 children per woman, which is attained in the first year projected and is held constant over the entire projection period. This is an upward revision of the most recent population projections published in 2005, which suggested a level of 1.51 children per woman.

According to this medium assumption, the mean age at childbearing would continue to rise, going from 29.75 years in 2007 to 30.17 years in 2009, an increase of about 0.4 years. It would then be held constant over the entire projection period.

The low and high assumptions were set at 1.50 and 1.90 children per woman at the national level. These levels are gradually reached by 2013/2014 and are

then held constant until the end of the projection period (Chart 1.1). The mean age at childbearing also increases according to these two assumptions, by 0.6 years and 0.2 years according to the low and high assumptions respectively.

Table 1.2 shows, for each province/territory, observed total fertility rates and those projected based on three assumptions derived from those developed at the national level. To build these assumptions, factors of variation were calculated at the national level and then applied to fertility rates by age for each province and territory in order to reach target total fertility rates and mean age at childbearing. In general, mirroring the situation that existed in 2007, Newfoundland and Labrador would have the lowest fertility under all three assumptions, and Nunavut would have the highest.

Chart 1.1
Total fertility rate observed (1971 to 2007) and projected (2008 to 2036) according to three assumptions, Canada

1.3.2 Rationale for assumptions

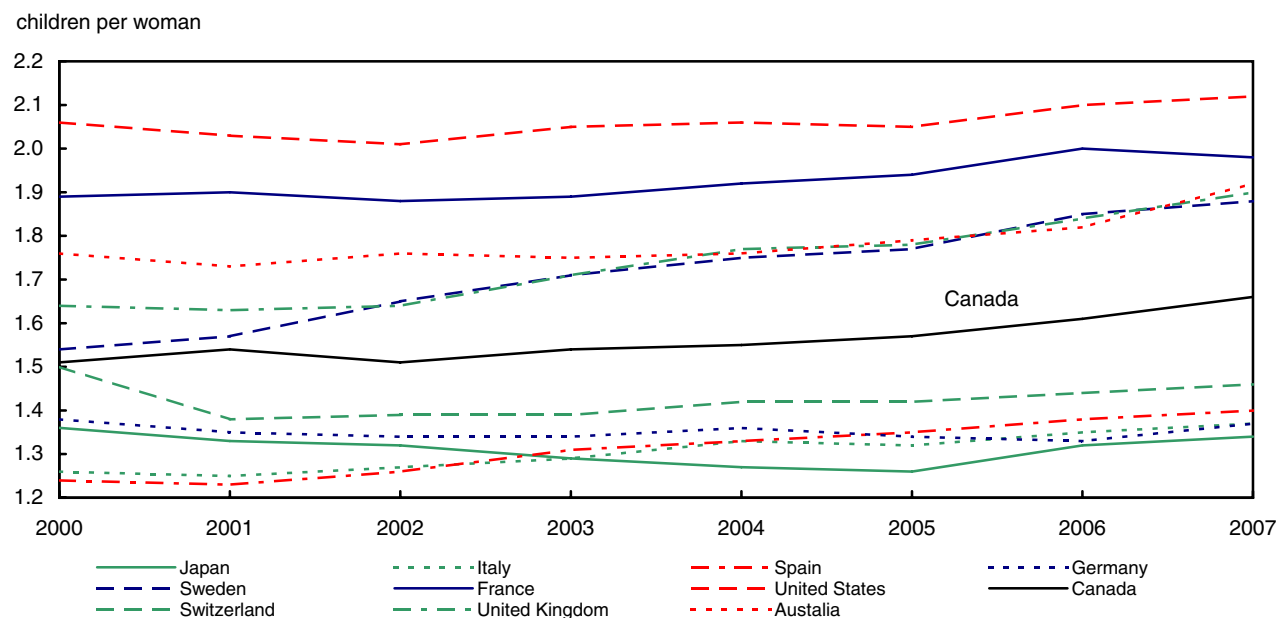

Several factors were considered when formulating the fertility assumptions for Canada. First, Canadian fertility has exhibited an upward movement since 2004, with the total fertility rate (TFR) going from 1.53 children per woman to 1.66 in 2007, the last available year for which these projections were produced. The level reached in 2007 was the highest since 1995, indicating that this was indeed a significant increase, observed over a period of just three years. Furthermore, birth data for 2008 released by some Canadian provinces show a continuation of the upward trend, suggesting that the TFR for Canada in 2008 will be even higher than in 2007. For example, in 2008, the TFR already exceeded 1.70 children per woman in Quebec (1.74) and 1.50 in British Columbia, the highest rates since 1976 and 1997 respectively. It was therefore appropriate to take these recent trends into account and to readjust the medium fertility assumption upward in comparison to the previous projection exercise.

The level of the completed fertility rate of Canadian women born between 1960 and 1975 was also considered in developing the medium assumption. The completed fertility rate of a cohort of women, such as those born in 1960, is the average number of children that those women will have actually had during their reproductive life. This indicator is useful for developing

fertility assumptions, since it is free from short-term or cyclical variations in fertility. While the TFR in Canada has fallen to levels close to 1.50 children per woman, no cohort of Canadian women thus far has reached a completed fertility rate of less than 1.76 children per woman, suggesting that a medium assumption close to this level is reasonable for mid to long-term projections over a 25-year period.

Finally, the medium assumption was established in light of the recent evolution of fertility in numerous industrialized countries. As in Canada, fertility in many countries has also risen in recent years, suggesting that the increase in Canada is not an isolated phenomenon. For example, fertility in the United Kingdom went from approximately 1.65 children per woman in 2001 to 1.90 children per woman in 2007 (Chart 1.2). It is interesting to note that Canada falls between two quite distinct groups. A first group, consisting of the United States, Australia and the United Kingdom (all Anglo-Saxon countries like Canada), France and Sweden, usually exhibits higher fertility. By contrast, Italy, Japan, Spain, Germany and Switzerland usually exhibit lower fertility. In light of these considerations, the median assumption was developed to preserve Canada's intermediate position while taking account of the upward movement observed in almost all these countries.

Chart 1.2
Total fertility rate observed for a selection of industrialised countries, 2000 to 2007

Source(s): Different statistical national agencies, Sardon (2004) and Eurostat.

The medium assumption also has the mean age at childbearing rise quickly from 29.75 years to 30.17 years. This is an increase of approximately 0.4 years, which extends a long upward trend seen in recent decades. Indeed, in 2005 the fertility rate of women aged 30 to 34 years exceeded that of women aged 25 to 29 years, showing that Canadian women are having their children at increasingly older ages. This assumption seems reasonable in light of the uninterrupted rise thus far in female labour force participation rates and the even greater upward shift in the age pattern of childbearing in some countries such as Australia.

The low assumption was set at 1.50 children per woman in view of how Canadian fertility has evolved in recent decades. This level roughly corresponds to the lowest level ever recorded in Canada (1.51 children per woman in 2000 and 2002). It also corresponds to the lowest fertility levels recorded in 2007 in Canadian provinces or territories (Newfoundland and Labrador, Nova Scotia, New Brunswick and British Columbia). This level is also slightly higher than the fertility recently recorded within the group of "low fertility" industrialized countries consisting of Germany, Japan, Italy, Switzerland and Spain. A final point is that some phenomena historically associated with low fertility are still on the rise: common-law unions, the participation

of women in the labour force and their average level of schooling. Possibly these phenomena will continue to exert downward pressure on Canadian fertility in the future.

The low assumption is associated with a greater upward shift in the age pattern of fertility, with the mean age at childbearing rising 0.6 years to 30.33 years. This level has already been recorded in some industrialized countries and therefore appears reasonable in light of past trends for this indicator.

The high assumption was set at 1.90 children per woman in light of the international context: this level is approximately the average level of fertility recently recorded in "high fertility" industrialized countries such as the United States, France, Australia, the United Kingdom and Sweden. This level is also slightly lower than the average fertility recorded in 2007 for the provinces where the highest fertility levels were recorded (Manitoba, Saskatchewan and Alberta). Lastly, it should be noted that this level has not been observed in Canada since 1972, and it is still below the replacement level (approximately 2.10 children per woman).

According to the high assumption, the mean age at childbearing would rise from 29.75 years to 29.96 years. The recent example of a number of

countries, especially Australia, shows that a slight upward shift in the age pattern of fertility is not incompatible with a significant rise in the fertility level. Since the mean age at childbearing has not declined in Canada since 1975, the high assumption adopted provides for that age to rise in the coming years, although the rise is more modest than under the low and medium assumptions.

1.4 Mortality

As with fertility, three assumptions were formulated regarding future Canadian mortality, a demographic component that can have a major effect on the size of Canada's old and very old populations. In the context of demographic aging, these groups are of particular interest.

The three assumptions formulated suggest a continuation of the secular decline of Canadian mortality, and hence a life expectancy at birth that would continue to rise in the coming years. The trends since 1921 are clear; they show that mortality has greatly declined over the past 90 years in Canada. Between 1921 and 2006, life expectancy grew by nearly 25 years for females and 22 years for males. However, the rate of increase in life expectancy has varied from one period to another; overall, the increase has been less rapid in recent decades than earlier in the twentieth century, especially for Canadian women.

The method used to project mortality is the same as was used in the previous edition of the population projections. It draws on a parametric model developed by Li and Lee (2005). That model is used to project mortality rates by age and sex in a consistent manner for all provinces, which largely reflects the fact that Canadian standards ensure a high degree of similarity in the health insurance plans of the provinces and territories.

The parameters of the Li and Lee model are derived from the change in mortality rates recorded over a given period, in this case the 1981 to 2006 interval. This period was chosen not only because it captures the recent pace of the decline in Canadian mortality, but also because it has the advantage of reflecting the narrowing of the gap in life expectancy between males and females.

The mortality of the territories was projected using the method based on recent differences in relation to the national average, since the populations of these regions are too small to obtain reliable parameters for the Li-Lee model. Unlike in the previous edition, each territory was treated individually this time.

The low and high assumptions were based on the 1% confidence intervals of the ARIMA model used to project a parameter of the equation used in the Li-Lee method. The use of these intervals yields a reasonable range for the future course of life expectancy for the provinces and territories.

1.4.1 Assumptions

Under the medium assumption, Canadian females' life expectancy at birth would increase from 82.9 years in 2006 to 87.3 years in 2036, a gain of 4.4 years in 30 years (Table 1.3). By comparison, the gain was 5.1 years between 1976 and 2006. For males, life expectancy would rise from 78.2 years in 2006 to 84.0 years in 2036, an increase of 5.8 years. During the period 1976 to 2006, the gain was larger, namely 7.8 years. The more rapid increase in male life expectancy means that the mortality gap between the two sexes would continue to narrow in the coming years, going from 4.7 years in 2006 to 3.3 years in 2036.

Table 1.3
Life expectancy at birth in 2006 and 2036 according to three assumptions, Canada, provinces and territories

	Males				Females			
	2006	2036			2006	2036		
		Assumption				Assumption		
		Low	Medium	High		Low	Medium	High
years								
Canada	78.2	82.3	84.0	85.4	82.9	86.0	87.3	88.4
Newfoundland and Labrador	75.5	80.0	81.7	83.3	80.7	84.1	85.5	86.7
Prince Edward Island	77.3	81.2	82.9	84.4	82.1	86.1	87.4	88.6
Nova Scotia	77.0	81.1	82.8	84.3	82.2	85.2	86.5	87.7
New Brunswick	77.6	81.7	83.4	84.9	82.5	85.6	86.8	88.0
Quebec	78.1	82.2	83.8	85.2	83.1	86.3	87.5	88.6
Ontario	78.7	82.8	84.4	85.8	83.1	86.1	87.3	88.4
Manitoba	76.9	81.3	83.1	84.7	81.8	85.4	86.8	88.0
Saskatchewan	76.7	81.2	82.9	84.5	82.0	85.4	86.7	87.9
Alberta	78.0	82.3	84.0	85.5	82.9	86.1	87.4	88.6
British Columbia	78.9	82.9	84.5	85.9	83.5	86.6	87.8	88.9
Yukon	75.2	78.7	80.3	81.7	79.7	83.4	84.6	85.6
Northwest Territory	73.7	78.7	80.3	81.7	80.8	83.4	84.6	85.6
Nunavut	69.1	74.5	76.0	77.3	75.6	77.8	78.9	79.9

Source(s): Statistics Canada, Demography Division.

From one province to another, differences in life expectancy would be fairly small in 2036, mirroring the situation in 2006 and reflecting the relative homogeneity of mortality in Canada. Among the provinces, Newfoundland and Labrador would have the lowest life expectancies in 2036, with 81.7 years for males and 85.5 years for females, and British Columbia would have the highest, at 84.5 years for males and 87.8 years for females.

The low assumption would have life expectancy rise only 3.1 years for females and 4.1 years for males by 2036; at that point, life expectancies would be 86.0 and 82.3 years respectively. On the other hand, the high assumption would have life expectancy rise more rapidly, by 5.5 years for females and 7.2 years for males, comparable to the rate recorded during the last 25 years. Under this assumption, life expectancy in 2036 would reach 88.4 and 85.4 years for females and males respectively.

All the assumptions suggest that the existing gap between male and female life expectancies will continue to narrow.

1.4.2 Rationale for assumptions

The future course of mortality has been much debated within the scientific community. Some people may believe that the extent to which life expectancy can continue to increase is unknown since mortality is already quite low at numerous ages. If knowledge, medicine and technology continue to advance, it is likely that future gains will have to be made against chronic illnesses such as cancer, which has been the leading cause of death in Canada for several years, or against diseases that mainly affect the very old population. Others think that the growing prevalence of various conditions among the young, such as obesity and the diseases associated with it, including diabetes and hypertension, could considerably slow the increase in life expectancy in the coming decades. Some also think that life expectancy at the population level is already approaching a limit, given existing health care systems. In this context, future gains would require major public investment, which cannot be taken for granted. In contrast, many scientists remain optimistic, stressing that life expectancy continues to increase despite the high level that it has already reached in some countries. Since the limits of human life are well beyond 100 years, these researchers stress that there is still considerable room for the life expectancy of a population to increase.

Whatever the case, Canadians, both male and female, have one of the world's highest life expectancies at birth. A comparison of life expectancies recorded during the 2007 to 2009 period shows that Canadian females were behind only French, Spanish, Swiss, Australian and Japanese females, with the latter at the forefront with a life expectancy of 86 years. Canadian males, for their part, were behind only Japanese, Swedish, Swiss, Australian and Icelandic males, with the latter leading with a life expectancy of 80 years. The assumptions developed take this situation into account; they propose life expectancies in 2036 that have never been observed to date, which would help maintain Canada among the countries with the highest life expectancies for both males and females.

1.5 International immigration

For some years now, Canadian population growth has been based more on migratory increase (i.e., excess of immigrants over emigrants) than on natural increase (excess of births over deaths). Considering that this situation is expected to continue over the coming decades because of low fertility and an aging population, the assumptions concerning this component take on great importance in this projection exercise.

Both the number of immigrants admitted annually to Canada and the immigration rate have sometimes varied considerably from year to year. For example, the immigration rate went from nearly 9.0 per thousand in 1993 to less than 6.0 per thousand in 1998, five years later. Even larger variations had been recorded in earlier decades. To take account of the sometimes fluctuating nature of immigration, three assumptions on future levels of immigration to Canada were formulated, as is usually the case in Statistics Canada projections.

1.5.1 Assumptions

The immigration assumptions were formulated for two periods. Firstly, the low, medium and high assumptions

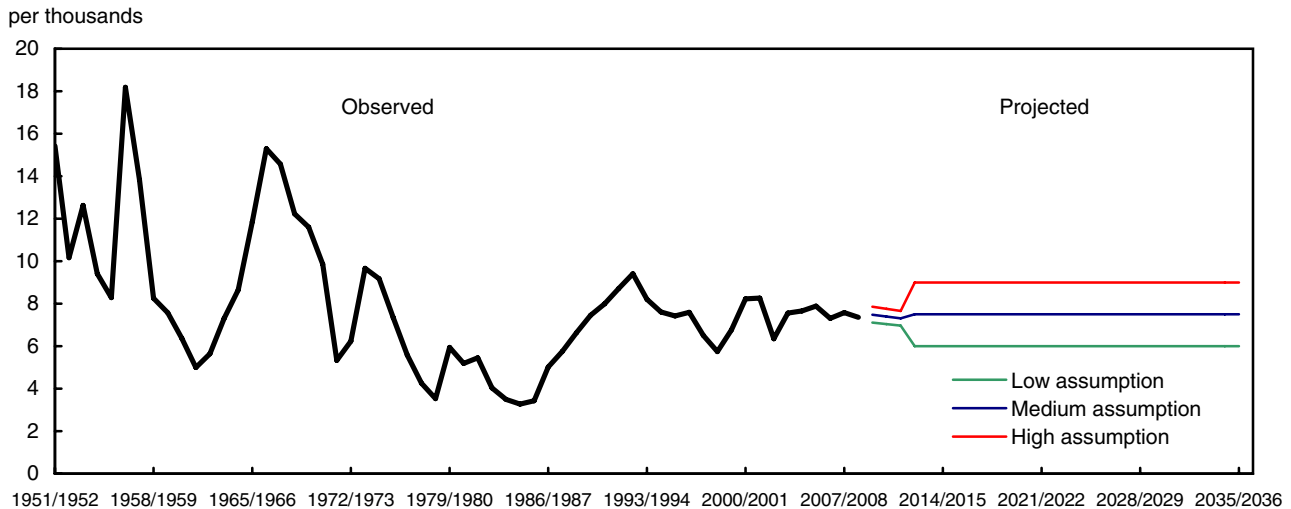

were, for the first three years of projections, directly drawn from the 2009 Immigration Plan as formulated by Citizenship and Immigration Canada (CIC). This range of immigrants, set out by CIC in its immigration plan for 2009, is considered the best estimate of the level of Canadian immigration in the short term. The Immigration Plan called for admitting between 240,000 (low assumption) and 265,000 (high assumption) immigrants to Canada in 2010. The medium assumption was set at the middle value of the range, namely 252,500 immigrants annually.

After the first three years of projection, the assumptions are based on immigration rates rather than numbers. Thus, the numbers of immigrants admitted to Canada evolve along with the projected population growth. The use of rates serves to prevent these rates from mechanically decreasing with every future population increase, an effect generated systematically when the assumptions are based on immigrant numbers held constant over the projection period. Finally, unlike in the previously published projections, where the numbers of immigrants reached in 2031 were held constant until 2056, the present assumptions use immigration rates until the end of the projection period for Canada, in 2061.

Under the medium assumption, the immigration rate would be 7.5 per thousand in Canada during the entire projection period, except, of course, for the first three years when the figures used are drawn from the Immigration Plan (Chart 1.3). That level is the average annual immigration rate for the period from 1991 to 2008.

The low assumption instead suggests that the immigration rate would be 6.0 per thousand between 2012/2013 and 2060/2061 in Canada. This level roughly corresponds to the lowest immigration rate recorded since 1991. Finally, the high assumption sets the immigration rate at 9.0 per thousand over the entire projection period, a level that instead corresponds to the highest rate recorded since 1991.

Chart 1.3
Immigration rate observed (1951/1952 to 2008/2009) and projected (2009/2010 to 2035/2036) according to three assumptions, Canada

Note(s): During the first three years of projection, the assumptions are based on the number of immigrants provided by the immigration plan of Citizenship and Immigration Canada. The denominator used to calculate the immigration rate corresponds to the host population, that is the mean Canadian population during a given period, and not the population at risk to immigrate to Canada.

Source(s): Citizenship and Immigration Canada and Statistics Canada, Demography Division.

The provincial distribution of Canadian immigration has changed in recent years. For example, a larger proportion of immigrants are settling in Manitoba and Alberta. Conversely, the proportion of immigrants who choose Ontario has been declining for several years, going from 60% to approximately 50%. To take these important changes into account, the distribution of immigrants admitted to Canada in the various provinces and territories was based on the average provincial distribution of immigrants during the period 2005/2006 to 2007/2008. This distribution is held constant over the entire projection period.

The same period was also used to distribute immigrants by age and sex. In regions that receive large contingents of immigrants, namely in Ontario, Quebec, British Columbia and Alberta, the distribution recorded for the province was used. In the case of Saskatchewan and Manitoba, the average distribution for these two provinces was used. Finally, the average national age and sex distribution was used in all other regions.

Table 1.4 shows the actual (2008/2009) and projected (2035/2036) immigrant numbers for Canada, the provinces and the territories according to the three assumptions used. Under the medium assumption, Canada would receive nearly 334,000 immigrants in 2035/2036, nearly half of whom (166,300) would settle in Ontario.

Table 1.4
Annual number of immigrants observed (2008/2009) and projected (2035/2036) according to three assumptions, Canada, provinces and territories

1.5.2 Rationale for assumptions

Immigration is a difficult component to project in the long run. In the short run, immigration levels are determined by the department responsible. Therefore, in addition to looking at recent immigration levels, it is appropriate to take other factors into consideration when formulating assumptions.

The high assumption sets the immigration rate at 9.0 per thousand, a rate that could reflect an increase aiming to meet Canada's future labour force needs. It is to be expected that many workers—most belonging to the baby boom generation, born between 1946 and 1965—will leave the labour force in the coming years to join the ranks of the elderly. Immigration could serve to bolster the labour force, which will need among other things to meet the needs of a rapidly growing elderly population.

The low assumption, which sets the immigration rate at 6.0 per thousand, is also plausible considering several factors. First, the economic integration of immigrants has seemed in recent years to be more difficult than it was previously. Second, the rapid economic development of some countries that sources of many recent immigrants to Canada—China and India in particular—could reduce the pool of potential candidates for immigration. Increased competition from

other industrialized countries for skilled immigrants could also affect Canada's ability to recruit the immigrants that it needs.

1.6 Emigration

Statistics Canada's population estimates and projections programs identify three components of emigration: emigrants, returning emigrants and the net number of persons temporarily abroad.

1.6.1 Emigrants

Emigrants are Canadian citizens or landed immigrants who have left Canada to settle permanently in another country. The number of emigrants has shown little change, averaging around 45,700 persons since the early 1990s. In light of this, a single assumption was formulated, taking the average emigration rates by age, sex and province/territory recorded during the period 1991/1992 to 2007/2008 and holding them constant throughout the entire projection period. Thus formulated, the assumption has the number of emigrants increasing from 48,800 in 2009/2010 to roughly 59,200 in 2035/2036 according to the medium-growth scenario (M1).

1.6.2 Returning emigrants

Returning emigrants are Canadian citizens or landed immigrants who emigrated from Canada and returned to settle there. Their number—a modest one—is estimated at approximately 23,500 annually since the start of the 2000s. The vast majority of returning emigrants are concentrated in four provinces: Ontario, Quebec, Alberta and British Columbia.

As in the preceding edition of the projections, the assumption formulated for returning emigrants is based on the relationship that exists between them and emigration, since the persons likely to return to Canada to settle are those who emigrated at some point in their lives. The projected number of returning emigrants is obtained by applying a returning migration rate to the number of emigrants generated by the projection model. This rate is set at 44.5%, the average for the period 1991/1992 to 2007/2008, the same period as for the assumption on emigration.

1.6.3 Persons temporarily abroad

Persons temporarily abroad are Canadian citizens or landed immigrants who are living abroad temporarily and no longer have a usual place of residence in Canada. The data available on this component yield an annual balance, rather than a number. A balance is the result of two flows, in this case consisting of persons leaving Canada (temporarily) and those returning.

Since the early 2000s, the annual net number of persons temporarily abroad has remained stable, averaging slightly more than 20,000, and is mostly attributable to four provinces: Ontario, Quebec, Alberta and British Columbia.

The assumption adopted in the present projections consists in taking the net annual average figure recorded during the period 2005/2006 to 2007/2008, namely 21,180 persons, and holding it constant until 2061. This level is very close to the average net figure for the period 1991/1992 to 2007/2008, reflecting the fact that this component has undergone few sizable variations over the past two decades.

Once again, the projections use a distribution by age, sex and province/territory derived from the average recorded for the period 2005/2006 to 2007/2008.

1.7 Non-permanent residents

Non-permanent residents include the following persons: persons residing in Canada who claim refugee status, persons who hold a work permit, a ministerial permit or a student visa, as well as members of their family living with them in Canada. The net annual number of non-permanent residents increased considerably in recent years, going from roughly 9,000 persons in 2004/2005 to more than 70,000 in 2008/2009. The increase was especially sizable for Alberta, British Columbia and Saskatchewan. Also, a new CIC class of immigrants, the Canadian Experience Class (CEC), allows non-permanent residents of Canada who meet certain conditions to file an application for permanent residence. This class could make the status of non-permanent residents in Canada more attractive and thus lead, in the coming years, to the maintenance of a high net annual figure. This is of particular interest in a context where many Canadians will soon be leaving the labour force.

The assumption adopted for non-permanent residents was therefore changed from the the previously published projections to reflect the recent changes. The assumption adopted suggests that the net annual figure would show a linear decline from approximately 51,000 in 2007/2008 to 0 in 2018/2019, during a period when departures from the labour force will quite probably be numerous. After 2018, the net number of non-permanent residents would be maintained at zero for the rest of the projection period. Thus, under this assumption, the stock of non-permanent residents in the Canadian population would rise from 500,000 in 2008 to just over 750,000 in 2018.

Again to reflect the recent changes, the distribution by age, sex and province/territory corresponds to the distribution recorded during the period 2005/2006 to 2007/2008. This distribution would be held constant over the entire projection period.

1.8 Interprovincial migration

Of all the components of population growth, interprovincial migration assumptions often generate the largest variations as to the projected size and growth of the population of the different provinces and territories. The strong volatility of interprovincial migration makes projection difficult; from year to year, variations in interprovincial net migration can be quite sizable and can, for example, shift from positive to negative. Also, because it is often associated with structural or economic factors (Coulombe, 2006; Bernard et al., 2009), interprovincial migration adds considerable uncertainty to projections at the provincial/territorial level.

For all these reasons, and in order to propose a reasonable range of possible future situations, four separate assumptions are provided for this component. Also, in developing these assumptions, a major constraint must be taken into account: the net interprovincial migration figures for all the provinces and territories must sum to zero.

1.8.1 Assumptions

The method used to project interprovincial migration is the same as in the preceding edition of the projections: first, out-migration rates by age and sex for each province/territory are calculated on the basis of reference periods selected by means of an analysis of past trends. Second, origin-destination matrixes are used to allocate interprovincial out-migrants among Canada's other provinces and territories. These origin-destination matrixes are calculated using the same reference periods as for the out-migration rates in order to keep the model consistent.

The four assumptions, each reflecting a past reference period, are as follows: "historical" trends (1981 to 2008), 1988 to 1996 trends, 2001 to 2006 trends and 2006 to 2008 trends.

- **Historical trends assumption (1981 to 2008)**

The purpose of this assumption is to reflect broad long-term trends in internal migration in Canada. Accordingly, the reference period for this assumption is the longest of the four assumptions developed for these projections, and it was set to extend

from 1981 to 2008. In particular, the analysis covering such a period identifies movements that are usually favourable to Western Canada, especially Alberta and British Columbia, and to Ontario, and less favourable to Eastern Canada, including Newfoundland and Labrador, Nova Scotia, New Brunswick and Quebec. This scenario generates the most favourable net interprovincial migration figures of any of the four assumptions for Ontario and Manitoba and the least favourable for Newfoundland and Labrador, the Northwest Territories and Yukon (Table 1.5).

- **1988 to 1996 trends assumption**

This assumption is based on the trends recorded during the period 1988 to 1996, which were favourable to British Columbia, with that province registering an average annual net interprovincial migration of almost 34,000 persons. This is the highest figure in all four assumptions for that province. Because of the continuing expansion of the emerging economies in Asia and the reduced presence of the manufacturing sector—then in crisis—in the province's economy, British Columbia has, in relative terms, been spared the economic difficulties experienced elsewhere in Canada. This assumption also generates the most favourable net migration for Prince Edward Island, Nova Scotia, New Brunswick, the Northwest Territories and Nunavut.

Conversely, this period generates the most unfavourable net interprovincial migration of all four assumptions for the three Prairie provinces: Manitoba, Saskatchewan and Alberta.

- **2001 to 2006 trends assumption**

The expansion of Alberta's economy, in particular the petroleum industry, had a not inconsiderable effect on internal migration movements in Canada. Indeed, Alberta has succeeded in attracting large numbers of workers for the past fifteen years, and the 2001 to 2006 assumption is designed to reflect this phenomenon. Obviously, this is the assumption that generates the most favourable figures of all four hypotheses for Alberta, but also for Quebec, which experienced strong economic growth during these years. Conversely, this scenario is the least favourable to British Columbia, whose average annual net interprovincial migration was barely more than 3,000.

Table 1.5
Average annual net interprovincial migration according to four projection assumptions, provinces and territories

• 2006 to 2008 trends assumption

Recently there have been a number of major changes in interprovincial migration. After 22 straight years of negative annual net migration for Saskatchewan, the trend reversed in 2006/2007, and that province has since had positive and steadily rising net migration. Thus in 2007/2008, Saskatchewan gained more than 4,000 persons in its exchanges with Canada's other provinces and territories.

The situation both in Newfoundland and Labrador and in Manitoba has also considerably changed quite recently. In Newfoundland and Labrador, for example, annual net interprovincial migration went from an average of -4,000 during the period 2004/2005 to 2006/2007 to -528 in 2007/2008. Net migration even became positive in 2008/2009 (preliminary data) after being negative without interruption for 24 years. Finally, Ontario's net migration has greatly deteriorated, plunging to levels not seen since the late 1990s, at nearly -17,000 persons per year on average during the period 2006/2007 to 2007/2008.

These changes are probably related in part to Canada's recent economic situation. Saskatchewan has seen major development in the mining and petroleum sectors that has stimulated its economic growth. Major investments in Newfoundland and Labrador have created a demand for skilled labour. Lastly, problems in the automotive sector in Ontario have contributed to the deterioration of its net interprovincial migration.

1. The scenarios are described in the next section.

The 2006 to 2008 assumption was developed to reflect these major changes. It generates the most favourable, or the least unfavourable, net interprovincial migration figures for Saskatchewan, Newfoundland and Labrador and Yukon and the most negative figures for Ontario, Quebec, New Brunswick, Nova Scotia, Prince Edward Island and Nunavut.

1.8.2 Projected figures

Charts 1.4 to 1.16 show the observed and projected net interprovincial migration figures for each province and territory during the period from 1981/1982 to 2035/2036 according to the different scenarios proposed.¹ Among other things, these charts show some effects of applying constant out-migration rates to populations whose size and structure may vary over time. The use of rates of out-migration, compared with the use of fixed numbers, has a number of advantages, one being that they take account of both the size of populations at risk of migrating and their evolving age structure. However, because the population at risk of leaving a region does not necessarily evolve at the same rate as populations at risk of coming to that region, there can be a change over time in the net migration rate.

This phenomenon may be explained as follows: if the population of a region grows less rapidly than the populations of other regions, that region will see its net migration improve, since departures will decline and arrivals will increase. The opposite is also true. Thus, provinces with lower growth rates, such as the Atlantic provinces, will see their net interprovincial

migration improve as the projection advances in time; conversely, provinces with high growth rates, notably Ontario, will see their net migration deteriorate over time. This effect is due to the fact that the assumptions

are based on constant out-migration rates and on invariable origin-destination matrixes. However, the effect is moderate in most regions.

Section 2

Selection of scenarios

The purpose of the different projection scenarios is to reflect the uncertainty associated with the future. These scenarios are constructed by combining a number of assumptions regarding the future evolution of each of the components of population growth.

The four medium-growth scenarios (M1, M2, M3 and M4) were developed on the basis of assumptions reflecting the medium trends observed in the past. However, they differ from each other in the interprovincial migration assumption adopted. Each scenario puts forward a separate assumption to reflect the volatility of this component.

The low-growth (L) and high-growth (H) scenarios bring together assumptions that are consistent with either lower or higher growth than in the medium-growth scenarios. For example, assumptions such as those that entail high fertility, high life expectancy and strong immigration are the foundation for the high-growth scenario. Essentially, these two scenarios are intended to provide a plausible and sufficiently broad range of projected numbers to take account of the uncertainties inherent in any projection exercise. Note that in these

two scenarios, the interprovincial migration assumption is the same, namely the assumption that is based on the period 1981/1982 to 2007/2008 and is used in medium-growth scenario M1.

As noted above, only one assumption was formulated for emigration, returning emigrants, persons temporarily abroad and non-permanent residents. The various projection scenarios therefore do not offer any variations for these components.

Combinations of the various assumptions yield a total of 108 different scenarios. The results of six of these scenarios are appended to this publication. However, the analysis of the results, presented in the section that follows, is basically limited to the low, medium and high-growth scenarios.

Finally, for the first time, the results of a new short-term scenario are now available. The analysis is presented separately in Section 4, and detailed results are also appended to this publication. Except for mortality, the assumptions in this scenario reflect the components observed during a single year, the most recent one for which data are available from Statistics Canada's Demographic Estimates Program.

Table 2.1
Assumptions of fertility, mortality, immigration, emigration, non-permanent residents and interprovincial migration

Components	Number of assumptions	Assumptions		
		Low	Medium	High
Fertility ¹	3	1.5 children per woman	1.7 children per woman	1.9 children per woman
Life expectancy in 2036 - Males	3	82.3 years	84.0 years	85.4 years
Life expectancy in 2036 - Females	3	86.0 years	87.3 years	88.4 years
Immigration rate ^{2,3}	3	6.0 per 1,000	7.5 per 1,000	9.0 per 1,000
Emigration rate	1	1.53 per 1,000	1.53 per 1,000	1.53 per 1,000
Returning emigrant rate	1	44.5%	44.5%	44.5%
Net temporary emigration	1	Average (20,173) of the period 2005/2006 to 2007/2008 2007/2008 (51,090) net reaching 0 in 10 years	Average (20,173) of the period 2005/2006 to 2007/2008 2007/2008 (51,090) net reaching 0 in 10 years	Average (20,173) of the period 2005/2006 to 2007/2008 2007/2008 (51,090) net reaching 0 in 10 years
Non-permanents residents	1	net reaching 0 in 10 years	net reaching 0 in 10 years	net reaching 0 in 10 years
Interprovincial migration ⁴	4	---	---	---

- Total fertility rate for low and high assumptions will be reached in five years.
- During the first three years of projections, the assumptions are based on the number of immigrants provided in the Immigration plan from Citizenship and Immigration Canada.
- The denominator used to calculate the immigration rate corresponds to the host population, that is the mean Canadian population during a given period, and not the population at risk to immigrate to Canada.
- For interprovincial migration, there are no high or low assumptions for provinces and territories. The four assumptions are based on different periods, that is, 1981 to 2008, 2006 to 2008, 1988 to 1996 and 2001 to 2006.

The projection horizon for this scenario is limited to five years so that behaviours observed for a single year are not reproduced over a long period. This short-term

scenario enables users to picture how the Canadian population might evolve if recent demographic patterns were to persist.

Table 2.2
Summary table presenting underlying assumptions to the six selected scenarios

Selected scenarios	Fertility	Life expectancy	Immigration	Interprovincial migration
L - Low-growth	Low	Low	Low	Historical trends (1981 to 2008)
M1 - Medium-growth, historical trends (1981 to 2008)	Medium	Medium	Medium	Historical trends (1981 to 2008)
M2 - Medium-growth, trends 2006 to 2008	Medium	Medium	Medium	2006 to 2008 trends
M3 - Medium-growth, trends 1988 to 1996	Medium	Medium	Medium	1988 to 1996 trends
M4 - Medium-growth, trends 2001 to 2006	Medium	Medium	Medium	2001 to 2006 trends
H - High-growth	High	High	High	Historical trends (1981 to 2008)

Section 3

Analysis of the results of the long-term projections

3.1 Cautionary note

The population projections produced by Statistics Canada's Demography Division are not predictions. They should instead be understood as an exercise designed to envisage what the Canadian population might become in the years ahead according to various scenarios of future change. For this reason, Statistics Canada always publishes several scenarios and formulates several assumptions concerning the main components of population growth. Accordingly, users are invited to consider several scenarios when they analyse the results of the projections.

It should also be kept in mind that the projections are intended to look ahead to what the Canadian population might be in 25 years, in 2036. For this reason, the assumptions made usually take account of observed historical trends, and not only the most recent ones. Users interested in getting a better grasp of the consequences of the most recent changes in Canadian demography are invited to consult the new "short-term" scenario that provides results with a five-year time horizon.

It should also be kept in mind that the accuracy of the projections produced depends on a number of factors, notably various events—economic crises, wars, natural catastrophes, for example—that are difficult to

predict and can affect the growth and composition of the Canadian population. For this reason, Statistics Canada makes sure to revise its population projections regularly, so that the context for them is taken into account.

3.2 Growth of Canada's population from 2009 to 2061

The Canadian population has grown substantially in recent years, going from 30.7 million in 2000 to 33.7 million in 2009. During that period, population growth increased steadily, going from 9.4 per thousand at the start of the period to 12.4 per thousand at the end. The results of the various scenarios published here show that this growth would continue over the next fifty years. However, the pace of this growth would gradually slow, starting at the beginning of the projection period. This slowing would continue for varying lengths of time depending on the scenario chosen, but in all cases it would fade by the end of the period.

Thus, according to the medium-growth scenario¹, the Canadian population would grow steadily, increasing from 33.7 million in 2009 to 43.8 million in 2036 and then to 52.6 million in 2061 (Chart 3.1). According to this perspective, the population would grow at an average annual rate of 11.8 per thousand at the start of the period and 7.4 per thousand in 2060/2061 (Chart 3.2). The average annual growth rate for the period from 2009 to 2061 would be 8.6 per thousand, which is lower than the rate recorded during the period from 1981 to 2009 (11.0 per thousand).

1. For simplicity, the wording "medium-growth scenario" usually refers to scenario M1 which uses historical trends for the assumption on interprovincial migration.

Chart 3.1
Population observed (1971 to 2009) and projected (2010 to 2061) according to three scenarios, Canada

Source(s): Statistics Canada, Demography Division.

According to the high-growth scenario, the Canadian population would go from 33.7 million in 2009 to 47.7 million in 2036, then to 63.8 million in 2061, almost doubling in 50 years. As a result of stronger immigration than in the medium-growth scenario as well as higher life expectancy and, above all, fertility moving closer to the replacement level, this scenario shows an increase that is not only continual but also strong until the end of the projection period. From 12.6 per thousand in 2009/2010, the average annual growth rate would decline slightly to 11.9 per thousand in 2060/2061.

The low-growth scenario offers a different picture; here again Canada would experience growth, but while that growth would be continual, it would fall off rapidly. Under this scenario, the Canadian population would go from 40.1 million in 2036 to 43.0 million in 2061. Thus, the population would grow at a rate of 10.8 per thousand in 2009/2010, then decline to 2.6 per thousand in 2060/2061.

Overall, the projections in the 2009 to 2036 edition yield different results from the preceding series of projections (2005 to 2031); they revise upward the

growth that Canada could experience. For example, the results of the medium-growth scenario in the current projections, whereby the Canadian population would reach 50.7 million in 2056, are similar to the high-growth scenario of the preceding projections, which projected a population of 49.7 million in 2056. This is because the assumptions formulated in the two projection series are different, in light of how Canadian demography has evolved recently. The major demographic shifts that have taken place since the preceding series were produced—most notably, increases in fertility and immigration—generally point toward assumptions more favourable to population growth.

3.3 Components of growth

Regardless of the scenario, the population would increase, but at a pace that would vary over time. Declining over much of the projection period, the growth rate would reach a plateau, then turn upward again toward 2054 (Chart 3.2). An analysis of the different components of population growth sheds light on the causes of these patterns.

Chart 3.2

Average annual growth rate observed (1971/1972 to 2008/2009) and projected (2009/2010 to 2060/2061) according to three scenarios, Canada

Source(s): Statistics Canada, Demography division.

3.3.1 Natural increase

Natural increase is the difference between births and deaths, and its change over time is determined by the intensity of fertility and mortality, but also by the age structure of the Canadian population and how it evolves. For deaths, all scenarios show a fairly steady increase, which would slow at the end of the period. According to the medium-growth scenario, the number of deaths would double during the period: it would go from 243,500 in 2009/2010 to 375,400 in 2035/2036, peak at 487,100 in 2058/2059, then decline to 486,900 in 2060/2061 (Chart 3.3). The number of deaths would parallel the growth of the population as well as its aging. It would accelerate appreciably as the large generation of baby boomers reaches the advanced ages, associated with high mortality.

Eventually, the increase in the number of deaths would slacken and the trend would even turn downward, marking the gradual end of the movement of baby boomers into the ages of high mortality. In 2061, the generation of baby boomers will have practically disappeared from the Canadian population; the youngest of them, born in 1965, will be 96 years of

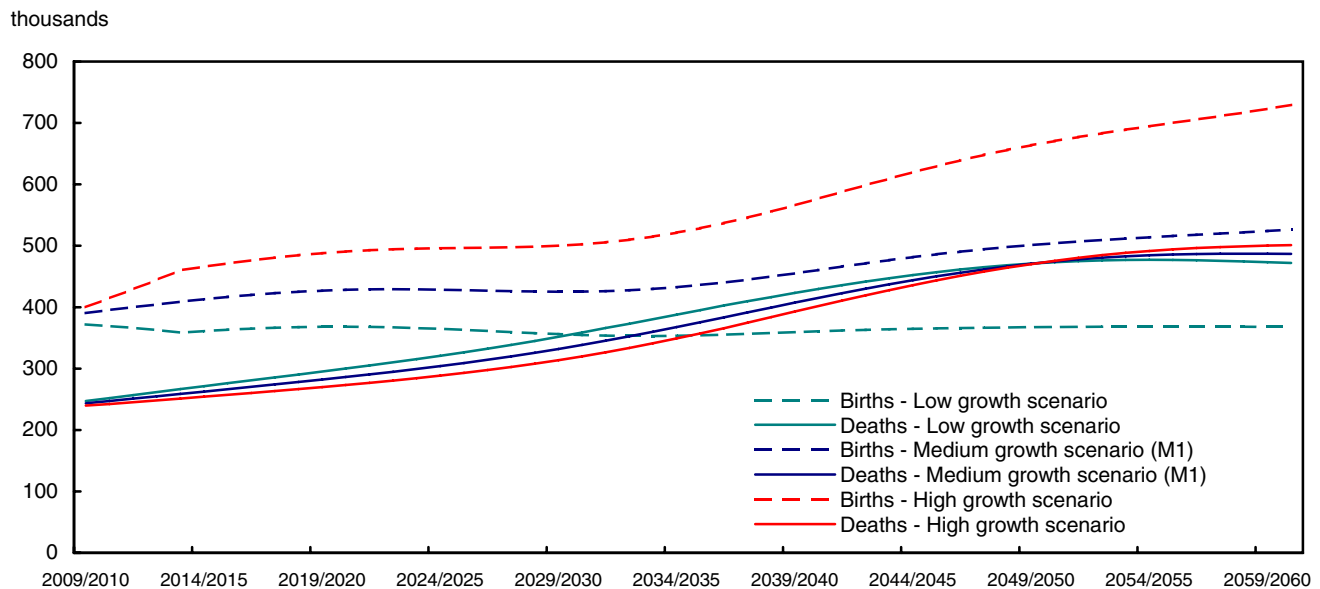

age. This is a noteworthy transition; throughout their lives, baby boomers will, as a consequence of their large numbers, have greatly influenced Canada's demographic landscape.

If the intensity of fertility is held constant, the projected number of births depends on changes in the numbers of women of childbearing age. The rise in their numbers at the start of the period accounts for part of the increase in births that is seen at the start of the projections in the medium and high-growth scenarios. Later, the number of births tends briefly to stabilize before starting to increase again until the end of the projected period.

However, it is important not to neglect the impact of another component, immigration, on how the number of births changes over time. Because a large proportion of immigrants are of childbearing age, strong immigration has a positive effect on the number of births.

According to the medium-growth scenario, the number of births, standing at 390,600 in 2009/2010, would rise to 429,300 in 2022/2023. It would then remain stable until 2029/2030 and would thereafter grow steadily, reaching 526,500 in 2060/2061.

Chart 3.3
Projected (2009/2010 to 2060/2061) births and deaths according to three scenarios, Canada

Source(s): Statistics Canada, Demography division.

In the medium-growth scenario, the number of deaths would approach the number of births at the end of the period but would never exceed it. Natural increase would therefore remain positive throughout the projected period. It would slightly rise at the start of the period and then fall substantially before edging up at the end of the period (Chart 3.4). The picture would be substantially the same in the high-growth scenario. Only in the low-growth scenario would natural increase become negative, beginning in 2030/2031.

3.3.2 Migratory increase

Until the early 1990s, natural growth has almost always been the main driver of population growth in Canada. In the middle of the 1990s however, a shift has occurred and migratory increase has become the main source of Canadian population growth, partly because of lower fertility, higher immigration and population aging.

In terms of numbers, migratory increase would proceed approximately at the same rate as the growth of the Canadian population, which reflects the fixed rates used in various assumptions for the international migration components. For example, according to the medium-growth scenario, the number of immigrants

would be 252,500 in 2009/2010, 333,600 in 2035/2036 and would reach 406,700 in 2060/2061.

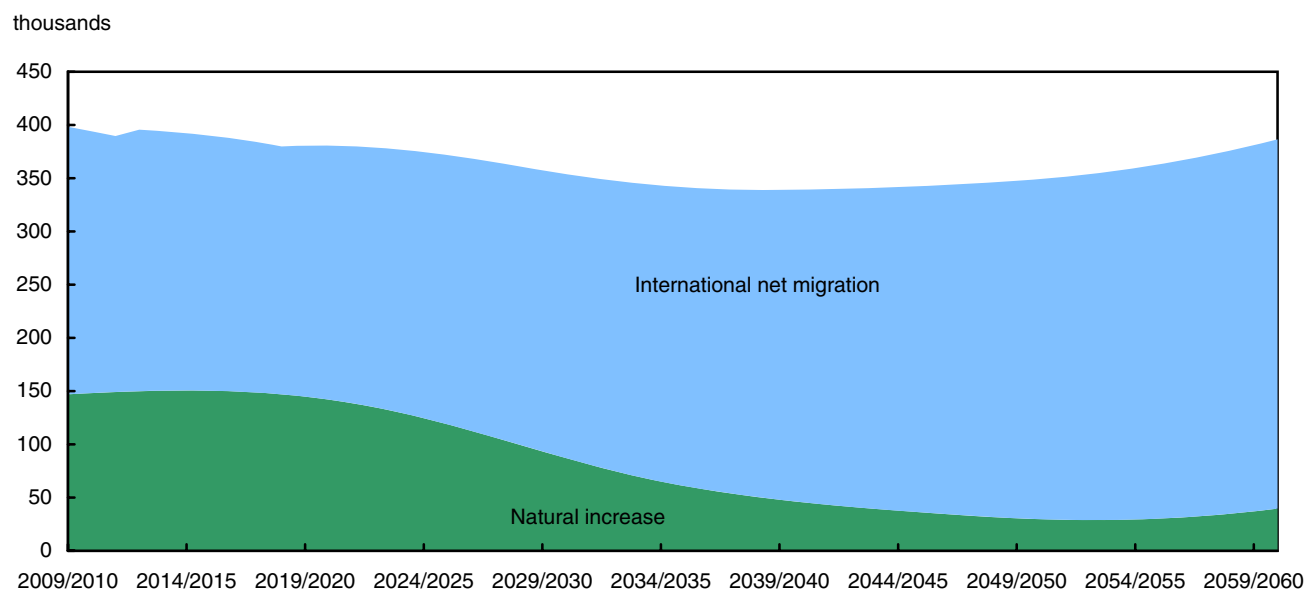

In the low and medium-growth scenarios, the decreasing importance of natural increase during almost all of the projected period, that is from 2009/2010 to 2055/2056 according to the low-growth scenario and from 2015/2016 to 2052/2053 according to the medium-growth scenario (Chart 3.4), would mean that population growth in Canada would rely more on migratory increase than on natural increase. In the case of the low-growth scenario, only migratory increase would contribute to population growth of the country, and this as early as 2030/2031.

In the high-growth scenario, natural increase would be on the rise at the beginning of the projection period up to 2018/2019, and from 2037/2038 to the end. However, the share of migratory increase in total population growth would still increase, mostly in the first part of the projection period, going from 60.6% in 2008/2009 to 71.7% by 2035/2036 and 72.1% by 2060/2061.

Thus, according to all selected scenarios, migratory increase would continue to represent an increasing share of future population growth.

Chart 3.4

Source(s): Statistics Canada, Demography Division.

3.4 Age structure of the Canadian population

According to all the projection scenarios, the Canadian population will continue to age over the coming decades. This process, which has been under way for a long time now, is integral to the current age structure of the population, and it will accelerate in the coming years. While cohorts that followed the baby boom are smaller because fertility is below the replacement level, all cohorts are enjoying a life expectancy that is steadily rising. Consequently, the demographic aging process would become more pronounced between 2010 and 2031, a period during which members of the baby boom generation will reach age 65. After that, aging would continue, but at a less rapid pace. The intensity of population aging varies depending on the projection scenarios chosen.

3.4.1 An evolving age pyramid

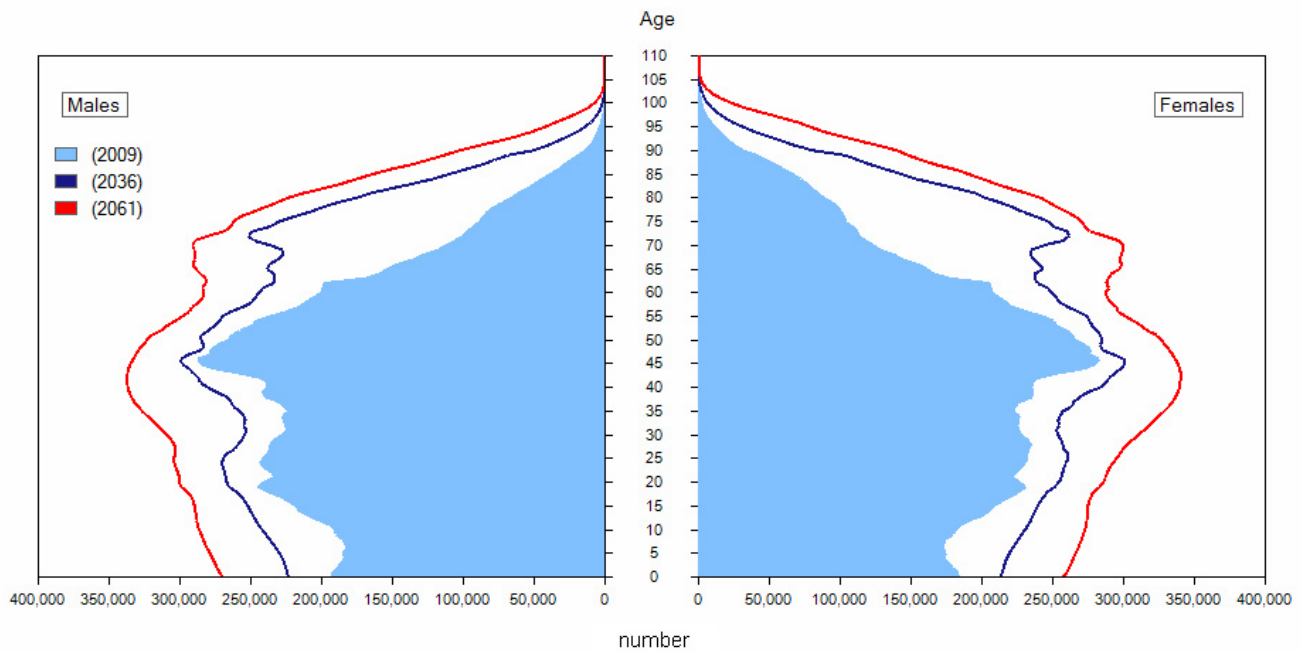

The age pyramid, which is a graphical representation of a population's structure by age and sex, sheds light on the changes that the Canadian population is destined to undergo in this regard. Thus, the age pyramid for the year 2009 (Chart 3.5) highlights the sizable demographic weight of the baby boom generation, whose members are aged 43 to 63. The generations born after the baby boomers are smaller, notably because of the low fertility seen in recent decades. This phenomenon is clearly illustrated by the fairly constant narrowing of the base of the pyramid.

According to the medium-growth scenario, the base of the age pyramid in 2036 should be broader than it was in 2009, and it would continue to broaden until 2061. The increase in the number of births, which is responsible for this broadening, mainly reflects two factors: the increase in fertility seen since 2002 and more women in childbearing age due to a positive demographic growth and immigrants' greater contribution.

However, the broadening of the pyramid would be perceptible at all ages, especially the advanced ages. In 2036, and even more so in 2061, the number of persons aged 65 years or over would be larger than in 2009 and the top of the pyramid would have a less slender appearance. Mortality would then be concentrated at very advanced ages,

and compared to 2009, would be distributed over a much narrower age range (Chart 3.6). This phenomenon is clearly illustrated by the increase in the modal age at death, which would go from 84 years in 2008/2009 to 88 years in 2035/2036 and then to 91 years in 2060/2061 according to the medium-growth scenario.

Source(s): Statistics Canada, Demography Division.

3.4.2 Distribution of the population by age groups

• Young people

The number of children (aged 0 to 14 years) reached 5.6 million in 2009, up slightly from 2008. This was the first increase in the number of children since 1996. According to the medium and high-growth scenarios, the number of children would increase each year. In the low-growth scenario, the number of children would grow until 2022 (increase of 213,600), would then decline until 2041 (decrease of 113,400), then rise again until the projection horizon in 2061 (increase of 201,300). Depending on the scenario, the number of children would range between 5.7 and 8.2 million in 2036 and between 5.9 and 11.1 million in 2061. According to the medium-growth scenario, the number of children would reach 6.9 million in 2036 and 8.2 million in 2061 (Chart 3.7).

• Seniors

In 2009, Canada had 4.7 million persons aged 65 years or over, twice the number recorded in 1981. According to all the projection scenarios, the growth of this group would accelerate in the coming years. By 2036, the number of seniors would more than double, ranging between 9.9 and 10.9 million depending on the scenario. In 2061, this number would range between 11.9 million and 15.0 million.

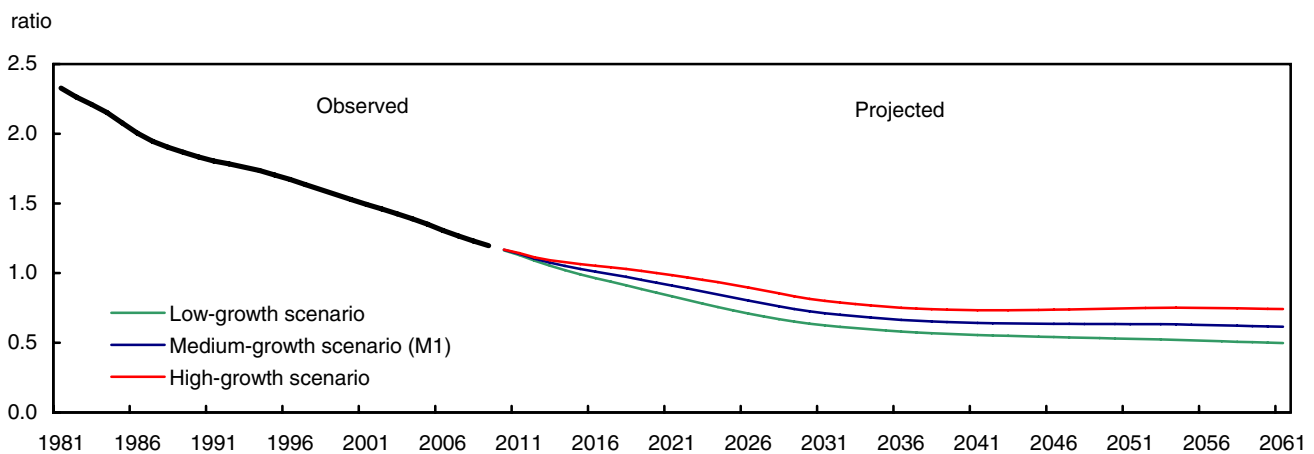

In 2009, Canada had 120 children per hundred seniors, a figure that had fallen by half since 1980. All the growth scenarios adopted show that this decline would continue in the coming years and the number of seniors would exceed the number of children in the near future. This reversal would occur in 2015 in the low-growth scenario and six years later in the high-growth scenario. This would be the first time in the history of the Canadian population that the number of persons aged 65 years or over exceeded the number of children under 15 years of age. Indeed, the children-seniors ratio would steadily diminish and would be between 58 and 75 children per hundred seniors in 2036 and between 50 and 74 in 2061 (Chart 3.8).

Chart 3.8
Ratio of the number of children aged 0 to 14 years to persons aged 65 years or over, observed (1981 to 2009) and projected (2010 to 2061), according to three scenarios, Canada

Source(s): Statistics Canada, Demography division.

• **Working-age population**

It is interesting to see how the 15-to-64 age group changes in size over time, since it includes most of the labour force and thus has an impact on the level of labour availability in Canada.² In 2009, this population accounted for approximately 69% of the Canadian population, a proportion that has risen since 1995 and is among the highest in industrialized countries. The corresponding proportion is 68% in Australia, 67% in the United States, 66% in France and the United Kingdom, 64% in Japan and 65% in the world as a whole.

However, according to all the scenarios adopted, the proportion of the population that is working age is bound to decline throughout the projection period. This decline would be especially rapid from the start of the projection until 2030, the year when the movement of

baby boomers into the 65 years or over age group is completed; after that, it would be more moderate. Thus, the proportion of the population aged 15 to 64 years would decline to approximately 60% in 2036. It would then remain relatively stable around this level (Chart 3.9).

Nevertheless, in 2061 the size of the working-age population would exceed the 2009 level, according to all the projection scenarios (Chart 3.7). In absolute numbers, the ranks of working-age persons would increase throughout the projected period, although at quite a variable rate; in the low-growth scenario, they would even decrease at times (Chart 3.10).

The narrow gap between the growth levels in the three scenarios during the initial three years of projection in Chart 3.10 is due to the use of constant immigrant numbers (obtained from the target range in the CIC Immigration Plan) that vary little from one scenario to another. Starting in 2012/2013, the immigration rates suggest greater divergence among the scenarios.

2. It is obviously a simplification to equate the large 15-to-64 age group with the working-age population, particularly given that some persons aged 65 or over are employed.

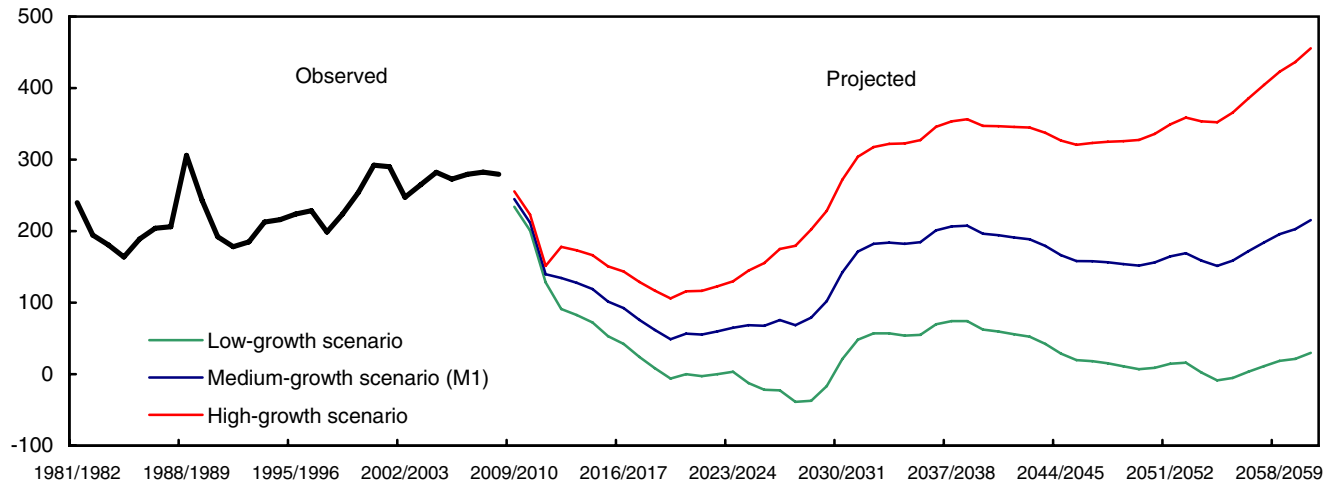

Chart 3.9
Proportion of population by age group, observed (1981 to 2009) and projected (2010 to 2061), according to three scenarios, Canada

Chart 3.10
Annual growth of the population aged 15 to 64 years, observed (1981/1982 to 2008/2009) and projected (2009/2010 to 2060/2061) according to three scenarios, Canada

thousands

Source(s): Statistics Canada, Demography Division.

The population aged 15 to 64 years grew steadily throughout the entire twentieth century, and in 2009 it stood at 23.4 million. According to the medium-growth scenario, it would reach 26.5 million in 2036 and 31.0 million in 2061. In the low-growth scenario, the population aged 15 to 64 years would reach 24.5 million in 2036 and would then grow more modestly, reaching 25.2 million in 2061. Finally, in the high-growth scenario, the working-age population would reach 28.7 million in 2036 and 37.6 million in 2061.

- **Demographic dependency ratio**

In 2009, the demographic dependency ratio, which indicates the number of persons aged 14 years or under or 65 years or over per hundred persons of

working age (15 to 64 years), was 44. Specifically, there were 24 young persons aged 14 years or under and 20 persons aged 65 years or over per hundred working-age persons. According to all the growth scenarios developed, the dependency ratio would increase rapidly until 2030 because of baby boomers reaching age 65 years and smaller cohorts replacing them (Chart 3.11). According to the scenarios, the demographic dependency ratio would reach approximately 65 years in 2036 and roughly 70 years in 2061. According to the medium-growth scenario, persons under 14 years and those aged 65 years or over would be equal in number in 2017, and then seniors would take the lead, so that by 2036 there would be 39 seniors and 26 children per hundred working-age persons.

Chart 3.11

3.4.3 Population aging

Canada has been an aging society for some time now. It is indicative of this phenomenon that the proportion of seniors (aged 65 years or over) within the population has steadily grown since 1960, going from 8% at that time to 14% in 2009. According to all projection scenarios adopted, this increase would continue in the coming years. The proportion of persons aged 65 years or over would range between 23% and 25% in 2036 and between 24% and 28% in 2061. In the medium-growth scenario, the proportion aged 65 years and over would

reach 24% in 2036 (Chart 3.9) and 25% in 2061. The increase in the proportion of seniors would be especially rapid in the next 25 years. Throughout this period at least, as shown by the age pyramids based on relative values (Chart 3.12), the increase would be more attributable to the growing number of persons aged 65 years and over than to changes seen in the 0-to-14 and 15-to-64 age groups. By contrast, the following 25 years, from 2036 to 2061, would see much more modest changes (Chart 3.13).

Chart 3.12
Age pyramids (in relative value) of the Canadian population, 2009 and 2036 (scenario M1)

Source(s): Statistics Canada, Demography Division.

Another indicator of the Canadian population's aging is the increase in the median age. The median age increased 10 years between 1981 and 2009, from 30 years to 40 years. The three projection scenarios adopted indicate that the median age would continue to increase at least until 2039. After that, it would continue to rise slightly in the low-growth scenario, would decrease slightly in the high-growth scenario and would tend to remain stable in the medium-growth scenario.

Starting in 2040, the relative stability in the median age occurs following the deaths of the baby boom generation and hence to the gradual emergence of a more regular age profile.

According to the scenarios, the median age would vary between 42 and 45 years in 2036 and between 42 and 47 years in 2061. In the medium-growth scenario, the median age would be stable at around 44 years during the period from 2036 to 2061 (Chart 3.14).

3.4.4 Very old age and centenarians

In 2009, the Canadian population had 1.3 million very old persons (aged 80 years or over), twice as many as in 1990. In all the projection scenarios, the number of very old persons would continue to increase rapidly in the coming years. According to the medium-growth scenario, the population aged 80 years or over would have increased 2.6 times by 2036 to 3.3 million, and 3.9 times by 2061 to more than 5.1 million (Chart 3.15). These major increases are due in large part to the baby boomers reaching these ages, and to a lesser extent to the gradual increase in life expectancy. Similarly, the change in the proportion of the population aged 65 years or over consisting of those aged 80 years or over varies as baby boomers move into the ages 65-79 years at the start of the period and into the ages 80 years or over in the middle of the period and finally as they gradually disappear at the end of the projection period (Chart 3.16). According to the medium-growth scenario, the proportion of people aged 80 years or over among the senior population (aged 65 years or over) would reach about one person out of three by 2036 and slightly less than two persons out of five by 2061.

The sex ratio of the very old population is the number of men aged 80 years or over per hundred women of the same age. This ratio has been far below 100 for a number of decades, because of higher male mortality at all ages. In 2009, the ratio was 58 men aged 80 years or over per hundred women. According to all the growth scenarios developed, this ratio would rise and would range between 72 and 75 men per hundred women in 2036 and between 75 and 80 men per hundred women in 2061 (Chart 3.17). The increase in the ratio would be mainly due to the reduction in the mortality gap between sexes.

The number of persons reaching very old ages is also bound to increase, according to the projection scenarios. From approximately 6,000 in 2009, the number of centenarians living in Canada could nearly triple and almost quadruple by 2036, depending on the scenario adopted. In 2061, their number would range between 61,000 and 99,000 depending on the scenario.

3.5 Growth of the population of the provinces and territories from 2009 to 2036

For population projections at the scale of the provinces and territories, there is one more factor responsible for variation than in projections for Canada as a whole, namely interprovincial migration. In fact, in some provinces, interprovincial migration is the component that has the greatest impact on recent population growth (Dion and Coulombe, 2008).

The projections results show that the most favourable scenarios and the most unfavourable scenarios for the population growth of each specific province and territory are not always the high and low-growth scenarios (scenarios L and H), but sometimes the medium-growth scenarios that feature especially favourable or unfavourable interprovincial migration. This situation is indicative of the importance of interprovincial migration in how the population of some provinces changes over time.

According to the scenarios adopted for these projections, only Newfoundland and Labrador might have a population smaller in 2036 than its estimated population in 2009, and only in certain scenarios (Table 3.1). This province would see its population decline in three of the six scenarios, namely in the low-growth scenario and in medium-growth scenarios M2 and M4.

For provinces other than Newfoundland and Labrador as well as the territories, the projected population in 2036 would in all cases be larger than the estimated population in 2009. However, the projected growth rate differs greatly from one province to another, and for a given province from one scenario to another (Table 3.2). Ontario and British Columbia would record average annual growth exceeding that of the Canadian population as a whole, in all six scenarios. Conversely, all scenarios suggest average annual growth below that of Canada in Quebec, the Atlantic provinces and Nunavut. For the rest, the picture is more varied. Projected average annual growth is above the national average in only one of the six growth scenarios in Saskatchewan, Manitoba and the Northwest Territories, in two of the six scenarios in Yukon and in five of the six scenarios in Alberta.

Source(s): Statistics Canada, Demography Division.

According to these scenarios, the demographic weight of the provinces within Canada is going to evolve between now and 2036 (Table 3.3). Ontario's population would reach between 16.1 million and 19.4 million in 2036, representing approximately 40% of the Canadian population, up from 38.7% in 2009. British Columbia, whose population was approximately 4.5 million in 2009, would see its demographic weight rise to more than 14.0% of the Canadian population, or even to 16.2% (7.1 million) according to the scenario that is most favourable to it. As for Alberta, according to

the different scenarios, its population would range between 4.6 million and 5.7 million, or 10.8% to 13.0% of the Canadian population.

Quebec, which would have a population of between 8.6 million and 10.0 million in 2036, would see its demographic weight go from 23.2% in 2009 to 21.4% in 2036 in the best case, although it would remain Canada's second largest province. Between 2.4 million and 2.7 million persons, or 5.4% to 6.0% of the Canadian population, would live in one of the Atlantic provinces in 2036, compared to 2.3 million,

or 6.9% of the population, in 2009. In Manitoba, the population could reach between 1.4 million and 1.7 million, and the province's demographic weight would change only slightly during the projected period. Finally, Saskatchewan would have between 1.1 million and 1.4 million inhabitants in 2036 depending on the scenario, and would at best see its demographic weight remain the same.

3.6 Age structure of the population of the provinces and territories

The age structure at the national level masks major provincial and territorial differences. These differences are generated by observed gaps between provinces and territories with respect to fertility and immigration, but also with respect to interprovincial migration. Table 3.4 shows the median age in the different provinces and territories according to the six scenarios.

Overall, regardless of the scenario chosen, the Atlantic provinces would have the oldest populations in Canada in 2036. Newfoundland and Labrador had the oldest population in Canada in 2009, and according to all the scenarios, it would continue to do so in 2036. These results largely reflect the lower fertility recorded in these provinces and especially in Newfoundland and Labrador. That said, the impact of other components such as immigration and interprovincial migration are

still important. As evidence, the projected median age varies greatly between the different medium-growth scenarios, which, it should be recalled, differ only in terms of interprovincial migration. Unlike what can be seen in the other provinces and territories, the highest median age is generated by a variant of the medium-growth scenario rather than by the low-growth scenario, even though the latter scenario features lower fertility and lower immigration (scenario M4 in Newfoundland and Labrador and New Brunswick, scenario M2 in Prince Edward Island and scenarios M2 and M4 in Nova Scotia).

Conversely, according to all scenarios, the projected populations would be youngest in Nunavut and in the Northwest Territories. These two territories stand out with relatively high fertility in relation to the other provinces and territories, and this generates a younger median age than elsewhere.

For their part, the provinces of Ontario, Manitoba and Alberta would have a median age below the Canadian average, regardless of the scenario chosen. Elsewhere, the picture would be more varied. For example, the projected median age is higher than the Canadian average for only one scenario in Saskatchewan, and on the contrary for all scenarios but one in British Columbia (in both cases, scenario M3).

Table 3.4
Median age observed (2009) and projected (2036) according to six scenarios, Canada, provinces and territories

	2009	Scenario (2036)					
		Low-growth scenario	Medium-growth scenario (M1)	Medium-growth scenario (M2)	Medium-growth scenario (M3)	Medium-growth scenario (M4)	High-growth scenario
		years					
Canada	39.5	44.9	43.6	43.6	43.6	43.6	42.3
Newfoundland and Labrador	42.9	50.7	49.8	50.0	49.5	50.8	48.9
Prince Edward Island	41.7	47.3	46.1	47.8	46.0	45.7	44.9
Nova Scotia	42.6	48.3	47.3	48.5	47.1	48.4	46.3
New Brunswick	42.4	49.1	48.1	49.1	47.8	49.3	47.0
Quebec	41.1	45.9	44.7	45.1	44.7	44.7	43.4
Ontario	39.2	44.6	43.2	43.5	43.4	43.3	42.0
Manitoba	37.7	42.5	40.9	40.6	41.3	40.9	39.3
Saskatchewan	37.7	44.1	42.6	41.7	43.6	43.2	41.1
Alberta	35.6	42.8	41.4	40.5	41.9	40.4	40.0
British Columbia	40.7	45.4	44.1	44.0	43.1	44.6	43.0
Yukon	39.0	43.0	41.7	45.0	38.8	44.8	40.4
Northwest Territories	31.5	39.9	38.2	36.5	38.2	36.5	36.6
Nunavut	24.2	27.1	25.3	26.7	24.2	25.7	23.5

Source(s): Statistics Canada, Demography Division.

With a median age of 35.6 years, Alberta was in 2009 the youngest province in Canada, excepting the particular situation of the Northwest Territories (31.5 years) and Nunavut (24.2 years). However, in 2036, Manitoba's median age would be lower than Alberta's in four of the six scenarios. The gap between the median ages of the youngest province and the oldest, which was 7.2 years in 2009, would range between 8.2 years (scenarios L and M3) and 10.4 years (scenario M4) in 2036. The high-growth scenario is always associated with the youngest median age, in all provinces and territories.

The proportion of persons aged 65 years or more would be much higher than in 2009, in all scenarios for each province and territory (Table 3.5). The Atlantic provinces and Quebec, in each of the scenarios presented, would have a larger proportion aged 65 years or over in 2036 than would Canada as a whole. Conversely, the corresponding proportion

would be smaller than the Canadian average in Ontario, Manitoba, Alberta, the Northwest Territories and Nunavut. In Yukon, the projected proportion of persons aged 65 years or over in 2036 would be larger than the national average only in scenario M4. This would also be the case in Saskatchewan in scenarios M3 and M4 and in British Columbia in scenarios L, M1 and M4.

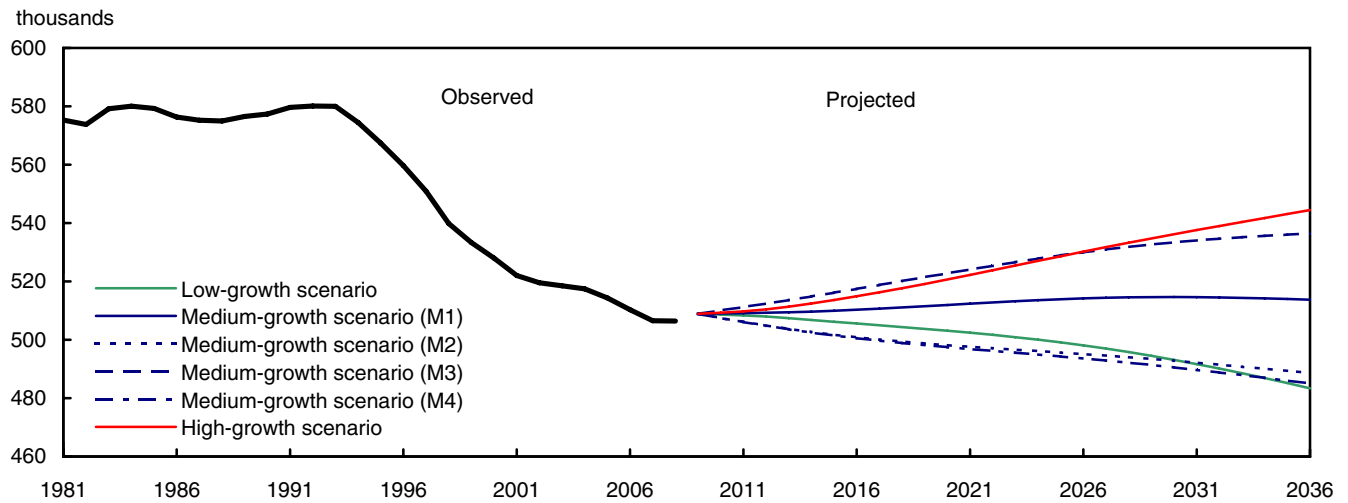

Overall, the disparities existing among the provinces in 2009 would tend to endure in the future, with some exceptions. The most striking example of this certainly Newfoundland and Labrador, where the proportion of persons aged 65 years or over was close to the Canadian average in 2009 (14.8% compared to 13.9%); in 2036, that province would consistently have Canada's highest proportion of persons aged 65 years or over (according to all scenarios). Charts 3.18 to 3.43 present the population and the age structure for each provinces and territories.

3.7 Sensitivity of results to projection assumptions

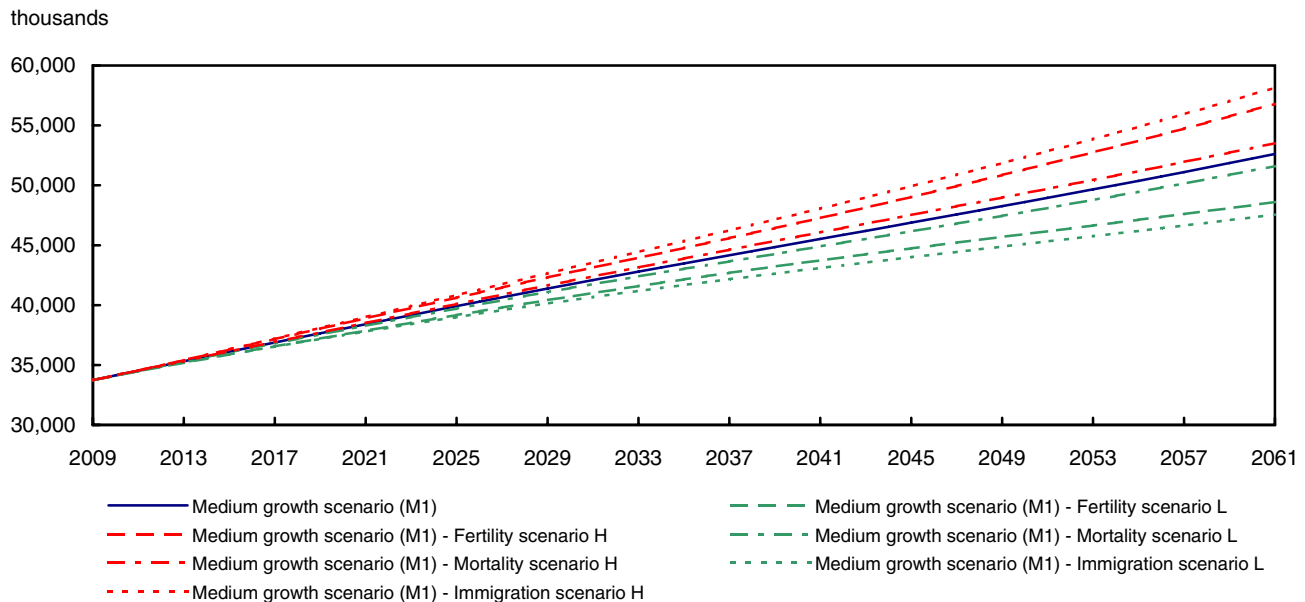

The above results for Canada according to the low, medium and high-growth scenarios stem from the combined effect of assumptions on immigration, fertility and life expectancy. In addition to reflecting the uncertainty associated with any population projection, these scenarios allow us to consider a large number of possibilities as to the future course of the population. However, it becomes difficult to determine the specific effect of each component on the structure and size of the population at the end of the projection period.

To analyse the sensitivity of the results to the projection assumptions and better understand the impact of each component, six analytical scenarios were created, based on medium-growth scenario M1. In them, a single assumption was modified. Scenarios 1 and 2 are intended to examine the impact of fertility. Scenario 1 is identical to scenario M1, except that it uses the low fertility assumption, the one used in the low-growth scenario. Scenario 2 does the same, except that in this case the high fertility assumption is adopted, the one

used in the high-growth scenario. In the same way, scenario M1 was modified by replacing the medium assumption by the low and high assumptions for the mortality component (scenarios 3 and 4) and the immigration component (scenarios 5 and 6).

Each of the three components has an effect on the size of the projected population, but immigration is the component with the greatest impact, followed by fertility (Chart 3.44). With low immigration (rate of 6.0 per thousand), the population would reach 47.6 million in 2061, whereas it would reach 58.2 million if immigration were high (rate of 9.0 per thousand), representing a difference of approximately 10.6 million. The difference is smaller but not insignificant between the low fertility scenario (1.5 children per woman) and the high fertility scenario (1.9 children per woman). In 2061, the difference between the two scenarios would be approximately 8.2 million. Finally, population growth would be much less affected by an acceleration or deceleration of the increase in life expectancy. Here the difference between the low and high scenarios would be approximately 1.9 million in 2061.

Chart 3.44
Population observed (2009) and projected (2010 to 2061) according to seven scenarios, Canada

Source(s): Statistics Canada, Demography Division.

Immigration therefore has a major impact on population size, but it is important to note that the impact varies considerably from one province to another. The provinces and territories that receive more immigrants in proportion to their population are naturally more sensitive to changes in the number of immigrants. Thus, while the population of Canada in 2036 would be 4.5% larger with the high immigration assumption than with the medium assumption, the percentage would vary between 5.4% and 4.8% in Ontario, British Columbia and Manitoba (Table 3.6).

While immigration and fertility levels both greatly influence the projected population figures, of the two, it is fertility that has the largest impact on the age structure of the population, which is most likely to either slow down or accelerate the aging of the Canadian population between now and 2061 (Chart 3.45). The scenarios that suggest fertility levels different from the medium scenario are those that feature the largest gap in the median age (4.5 years). The median age projected with the low fertility assumption would be 46.4 years, whereas it would be only 41.9 years with the high fertility assumption. The low fertility

assumption generates a smaller number of births, which has the consequence of accelerating the aging of the population by reducing the number of young people in relation to seniors. Higher fertility has exactly the opposite effect. Immigration and mortality levels also influence the median age and aging, but much more modestly. The scenarios that differ from the medium scenario only in their immigration level have a median age gap of approximately one year, as do those that differ only in their mortality level. Clearly, variations in mortality and immigration have a limited impact on the aging of the Canadian population.³

It is important to note that if other assumptions had been chosen, this would have led to conclusions different from those presented here. High and low assumptions calling for smaller or greater differences in relation to the medium scenario could change the order of importance of the effects of phenomena, especially for fertility and immigration.

3. Many studies, including Loh and George (2007), Guillemette and Robson (2006) and United Nations (2000), show that variations in the immigration level have a much greater effect on the size of the projected population than on its age structure.

Section 4

Analysis of the results of the short-term projections

The assumptions in the short-term scenario are based on the most recent data available when the projections were produced. For fertility, the parameters are based on births in 2007. For mortality, the parameters are exactly the same as in the long-term medium-growth scenarios, and they therefore project the same gains in life expectancy. Lastly, for the other components¹, preliminary data for the 2008/2009 period of the Demographic Estimates Program were used (Table 4.1). Since it is unlikely that the situation observed over a single year will continue over a long period, the projection horizon for this scenario is limited to five years.

According to the short-term scenario, Canada's population could reach 35.9 million in 2014, up 2.1 million from 2009. This represents an average annual growth rate of 12.4 per thousand (Table 4.2). About two-thirds of this growth would come from migratory increase, while the remaining one-third would result from natural increase.

All the provinces and territories would see their population grow during the next five years, except

for the Northwest Territories. For the Western provinces, Yukon and Nunavut, the growth of the population would be above the Canadian average. Alberta would lead with an average annual growth rate of 24.4 per thousand. Saskatchewan, Nunavut and British Columbia would follow, with growth rates of 16.9, 16.5 and 16.3 per thousand, respectively.

In absolute numbers, over the five-year period, Ontario would have the largest population increase (702,600), followed by Alberta (471,900), British Columbia (374,800) and Quebec (356,900).

The total migratory increase (the sum of net international migration and net interprovincial migration) would be the primary factor contributing to population growth, except in Nunavut and Northwest Territories where the migratory increase is negative and the fertility levels are higher than elsewhere in the country.

The Northwest Territories would be the only region of Canada to see its population decline during the five-year period, with natural increase and immigration not offsetting the losses from interprovincial migration. The Northwest Territories would therefore face a modest decline of 723 (-16.6 per thousand) during the period.

1. Projected net interprovincial migration according to every scenarios including the short-term scenario are shown for every province and territory in Charts 1.4 to 1.16 in Section 1.

Table 4.1
Assumptions of fertility, mortality, immigration, emigration, non-permanent residents and interprovincial migration

Components	Assumptions short-term scenario
Fertility	1.7 children per woman
Life expectancy in 2014 - Males	79.9 years
Life expectancy in 2014 - Females	84.2 years
Immigration	Immigration plan of Citizenship and Immigration Canada (252,500 per year)
Emigration rate	2008/2009 rate 1.30 per 1,000
Returning immigrant rate	2008/2009 rate 58.4%
Net temporary emigration	2008/2009 net (40,300)
Non-permanents residents	2008/2009 net (70,400)
Interprovincial migration	2008/2009 trend

Growth, while positive, would be modest in the Atlantic provinces. New Brunswick would experience the lowest average annual growth with a change of only 2.7 per thousand, followed by Nova Scotia (3.6 per thousand) and Newfoundland and Labrador (5.8 per thousand). Within this group, Newfoundland and Labrador would be the only province to experience negative natural increase, mainly due to low fertility.

Its growth would be heavily dependent on positive net interprovincial migration. This latter component was not inconsiderable in 2008/2009, and is reflected in the short-term scenario. As for Prince Edward Island, it would experience an average annual growth of 11.6 per thousand, much of it from international migration. Note that this province saw its share of immigrants increase considerably during the period 2008/2009.

Section 5

Analysis of previous editions of the projections

Using the components method, Statistics Canada has produced population projections of Canada, the provinces and the territories seven times since 1974. From one edition to another, the results vary considerably, insofar as each edition revises the preceding assumptions in light of more recent trends.

The current projections (2009 to 2036) revise upward the projected population levels of the preceding edition (2005 to 2031). These differences are largely attributable to increased fertility, the increase in the number of immigrants and positive net figures for non-permanent residents in the early years of the period. Already in 2009, the estimated population exceeded the projected population in the high-growth scenario of the 2005 to 2031 edition.

The same is true for the 2000 to 2026 edition. Proposing a total fertility rate of 1.8 that would be reached only in 2026, the high-growth scenario of the 2000 to 2026 edition underestimated births and non-permanent residents while it overestimated deaths.

This said, some caution is required in making comparisons with relatively recent editions of the projections, since such comparisons involve judging how long-term projections match actual values soon after their publication. But what about projections published longer ago? Clearly, even if the period covered by those projections has ended, it is instructive to study the results of the edition which was published in 1974¹ and which projected the population for the period 1972 to 2001. That edition was relatively successful in estimating the growth of the population (Chart 5.1). The medium-growth scenario suggested that the Canadian population would reach 31,050,000 in 2001, which is very close to the estimated population of 31,020,000.² However, care should be taken not to attribute this result to the

accuracy of the assumptions underlying that scenario. Those assumptions called for a total fertility rate of 2.20 children per woman to be reached in 1985 and an annual number of immigrants of 120,000. In 2001, the total fertility rate was instead 1.54 children per woman and the number of immigrants was more than double. These divergences were important: the age structure that existed in 2001 differs greatly from the one projected for the same year by the 1972 to 2001 edition, in which, among other things, the very young population was much more heavily represented (Chart 5.2).

In subsequent editions, the growth of the Canadian population closely followed the levels projected by the high-growth scenarios. The range suggested by the 1976 to 2001 edition just manages to capture the level reached in 2001, but this is not the case with the 1984 to 2006 and 1989 to 2011 editions, which underestimated growth (Chart 5.3). The underestimation of future immigration levels, which increased significantly in the early 1990s, largely explains why these editions aimed below the actual levels.

Produced after a period during which fertility and immigration underwent major increases, the 1993 to 2016 edition stands out: in its medium-growth scenario, it proposed a total fertility rate of 1.7 children per woman and an annual number of immigrants of 250,000, which is very similar to the assumptions adopted for the medium scenario of the current edition of the projections. In the short run, fertility rates and immigration did not remain at those levels, with the result that those projections overestimated the growth of the Canadian population over the period 1991 to 2009 while suggesting a younger age structure. However, the range offered by those projections encompasses the actual levels starting in 2004.

1. This was Statistics Canada's first publication on the subject.

2. This is a revised level to take account of retroactive adjustments made to the population estimates after the publication of these projections. Among other things, the adjustments served to take net undercoverage into account and to add components not formerly estimated, such as non-permanent residents and returning emigrants.

In short, past editions have often tended to underestimate Canada's population growth. Moreover, even in the high-growth scenarios, they most often showed growth falling off in the long run. One reason for this slowing of growth is that for immigration (a component that continues to play an expanding role in the Canada's population growth), the number of immigrants annually projected was fixed, and thus it generated a contribution to growth that grew proportionally smaller as the population increased.³ In the current edition of the projections, immigration

is projected according to a fixed rate (rather than a fixed number), which results in an annual contingent of immigrants that evolves in proportion to the size of the population. Added to relatively high fertility reaching 1.9 children per woman starting in 2013 and, at the end of the period, the near or total disappearance of the baby boom generation, immigration contributes to a much higher growth curve in the high-growth scenario than was seen in previous editions. Overall, it is perhaps this trend that distinguishes the current edition of the projections from those published previously.

3. In the 2005/2031 edition, an immigration rate was used until 2030/2031, followed by fixed numbers of immigrants (namely the numbers projected for 2030/2031 using a rate) from 2031/2032 to 2055/2056.

Section 6

Conclusion

The results of these projections differ from the preceding edition, as they highlight the recent changes that point to substantial population growth in the future, in keeping with the recent rise in fertility and the more long-standing increase in international immigration. In fact, according to the medium-growth scenario, the Canadian population should continue to grow in the next fifty years, at an average annual rate of 8.6 per thousand. While lower than the growth rate recorded during the period 1981 to 2009 (11.0 per thousand), this rate is higher than the rate projected by the medium-growth scenario of the preceding edition (2.4 per thousand). Moreover, the Canadian population would not decrease in any of the projection scenarios, which is another difference from the preceding edition.

Nevertheless, these changes would not be large enough to alter some trends that began some time ago, such as the aging of the population, the unequal growth of the provinces and territories or the increasing importance of immigration in population growth. It seems likely that in the future, these trends will continue to pose some challenges for Canada.

Finally, the 2008 United Nations projections indicate that the G8 countries might follow quite different paths in the future. In those projections, Italy, Germany, Japan and Russia would experience substantial population declines by the year 2050. Conversely, the United States, France and the United Kingdom, like Canada, would see their populations continue to grow until at least 2050.

Methodology and data quality

The methods used for these population projections are explained in detail in section 1– Methods and assumptions –and section 2 – Selection of scenarios – of this document. Users will also find in these sections information relating to data quality.

It is also worth noting that the accuracy of any projection is conditional on the reliability of the base population estimates, the component data, and the degree to which the underlying assumptions correspond to future trends. **Projections are not predictions**; they are instead an effort to create plausible scenarios based on assumptions regarding the components of population growth, which are themselves subject to uncertainty. Accordingly, it cannot be claimed that the values observed in the coming years will always remain within the range implied by the low-growth and high-growth scenarios.

Glossary

Ageing (of a population): An increase in the number of old persons as a percentage of the total population.

Baby boom period: The period following World War II, 1946 to 1965, marked by an important increase in fertility rates and in the absolute number of births.

Base population: Population used as the starting point for a population projection.

Cohort: Represents a group of persons who have experienced a specific demographic event during a given year. In the case of births, persons born within a specified year are referred to as a generation.

Components of population growth: Births, deaths and migration are components that alter the size of the total population and its composition by age and sex.

Demographic dependency ratio: Number of persons aged 14 or under and 65 or over per persons of working age (15 to 64).

Emigrant: Canadian citizen or immigrant who left Canada to settle permanently in another country.

Generation: Refers to a group of persons born within a given period. The 2006 generation represents people born during the year 2006.

Immigrant: Person who has been granted the right to live in Canada permanently by immigration authorities.

Interprovincial migration: Movement from one province to another involving a permanent change in residence. A person who takes up residence in another province or territory is an out-migrant with reference to the province or territory of origin, and an in-migrant with reference to the province or territory of destination.

Life expectancy: A statistical measure derived from the life table indicating the average number of years of life remaining for a population at a specific age x , if the people comprising that population would experience the mortality rates observed in a given year during their lives.

Median age: Age " x ", such that exactly one half of the population is older than " x " and the other half is younger than " x ".

Migratory increase: Difference between the number of migrants who settle within a geographic area and the number of migrants who leave that same area during a given period.

Mortality life table: A description of the extinction, age by age, of a hypothetical cohort according to the mortality observed a given year.

Natural increase: Difference between the number of births and the number of deaths during a given period.

Net emigration or total emigration: Number of emigrants minus the number of returning emigrants plus net temporary emigration.

Net international migration: Variation obtained according to the following formula: Immigrants + returning emigrants + net non-permanent residents – (emigrants + net temporary emigration).

Net interprovincial migration: Difference between in-migrants and out-migrants for a given province or territory.

Net migration: Difference between immigration and emigration or in-migration and out-migration for a given area and period of time.

Net non-permanent residents: Net non-permanent residents represent the variation in the number of non-permanent residents between two dates.

Net temporary emigration: Variation in the number of temporary emigrants between two dates.

Net undercoverage: Difference between the number of persons who were covered by the census but who were not enumerated (undercoverage) and the number of persons who were enumerated whereas they should not have been or who were enumerated more than once (overcoverage).

Non-permanent residents: Persons from another country who had an employment authorization, a student authorization, or a Minister's permit, or who were refugees claimants, and family members living with them.

Population increase or total increase: Change in the size of a population between two dates. It can also be obtained by summing natural increase and migratory increase.

Population pyramid: Bar chart that shows the distribution of a population by age and sex.

Projection scenario: Set of assumptions relating to the demographic components used to make a population projection.

Rate: Refers to the ratio of the number of events estimated in a year ($t, t+1$) to the average populations at the beginning and the end of the period. Crude rates are rates computed for an entire population. Specific rates are rates computed for a specific subgroup – usually the population at risk of having the event occurs. Thus, rates can be age-specific, sex-specific, etc.

Replacement level: Mean number of births per woman necessary to assure the long-term replacement of a population for a given mortality level. Currently, the replacement level in Canada is about 2.1 children per woman.

Returning emigrant: Canadian citizen or immigrant who have previously emigrated from Canada and who returns to settle in Canada.

Sex ratio: Ratio of males to females in a given population. It is usually expressed as the number of males per 100 females.

Temporary emigrant or persons temporarily abroad: Canadian citizen or immigrant who left Canada to settle temporarily in a foreign country.

Total fertility rate: The sum of age-specific fertility rates during a given year. It indicates the average number of children that a generation of women would have if, over the course of their reproductive life, they had fertility rates identical to those of the year considered.
